MAGAZINE REVIEWS.

"FLOODS and Their Causes" is the title of an article by Felix L. Oswald in Lippincott's Magazine for August, which is of peculiar interest in this year of freshets and floods. Some of the causes assigned are those which are beyond the control of man, such as the sudden melting of heavy bodies of snow, ice-gorges, occurring chiefly in rivers flowing from south to north, phenomenal rainfalls, an instance being given where 31 inches of rain fell in France in 20 hours, land-slides, volcanic eruptions, etc. The Johnstown flood is attributed to a "combination of unlucky circumtances." But the chief cause of river-floods in their most destructive form, is the disappearance of the forests from the highlands where the streams have their sources. Such calamities may be averted to a great extent by the preservation of the highland forests, and, at the same time, more favorable climatic conditions be secured to the residents of the valleys and plains. History supports this view of the case, as what were once some of the most fertile regions of the Old World, are, owing to forest destruction, now barren wastes.

Patriotic Americans never tire of reminiscences of Lincoln. His quaint humor, his simplicity, his intense love of justice, his tenderness of heart have endeared him to the common people. James M. Scovel gives numerous personal recollections which will tend to strengthen our affectionate regard for the martyred President.

Rollo Ogden contributes "A Literary Boarder," a semi-humorous tale of the college-educated son of a pork-packer, who secluded himself in an out-of-the-way country place to do some "literary work," to the great disgust of his hard-headed father, who in common with a "certain dark-eyed young lady" was much rejoiced to find him "cured of his nonsense," and ready to return to the parental roof. The complete novel is by William H. Babcock—"An Invention of the Enemy." The other departments are well filled and interesting as usual. J. B. Lippincott Company, Philadelphia, Pa.

THE WRITER, a monthly magazine to interest and help all literary workers, contains much to aid both professionals and amateurs. There are some young writers who have, and many more who think they have, literary ability. Such will find helpful information in this magazine. The Writer, Boston, Mass. Subscription price $1 per annum.

A SALARY with expenses paid will come handy to any one who is now out of employment, especially where no previous experience is required to get the position. If you want a position, see advertisement on page 519, headed, "A Chance to Make Money."—*Adv.*

Market Notes.

A JERSEYMAN'S JOTTINGS.

SOME MARKET PROSPECTS.

DURING the summer and fall I come into New York quite frequently. Most of my market stuff is sold in the city. I find that it pays pretty well to go and see the commission men from time to time. It does them no harm to understand that you are looking after your own interests. I have studied the markets for a number of years. Just about this time every year straws begin to move in the direction of future prices. There are some signs that rarely fail, though of course, much depends upon local conditions, particularly for market truck. I usually wait until I get the July report of the Department of Agriculture, add to that the information marketmen have given me and then make an estimate. I will give a portion of it to the RURAL this year. Take it for what it is worth. I don't guarantee it, but simply give a condensation of all the facts I have been able to obtain.

Wheat.—Mr. Dodge, at Washington, states that winter wheat will be about up to an average crop. The principal winter wheat States will produce good crops. Spring wheat is less favorable. The Dakota crop has been cut by drought and on the whole the crop will be below that of last year. American farmers are naturally concerned in the condition of the crop in Europe because the amount of grain taken out of the country will go far toward determining the price of that consumed here. From the information at hand now the probabilities are that the European crop will be about an average one, The prospects are better than usual, in England, France, Germany, Spain and Italy, medium in Austria and considerably worse than usual in Russia. The crop in India is below that of last year. As matters stand now, therefore, it may be said that American wheat ought to bring a good price.

Corn.—America has practically a monopoly in the production of this crop. We supply the world, though the Argentine Republic is now demanding a share of the trade. The English want this grain more for feeding to stock than for human consumption. A high price will lead them to use more linseed-meal and less corn-meal. There is every prospect now that prices for corn will rule high. The rainy spring delayed planting and hurt the crop besides, cut worms have been at work in the West, and other circumstances have reduced the crop. For some years past Eastern farmers have been reducing their corn acreage because Western corn was poured into local markets cheaper than the home product could be grown. Now when the Western corn fields are injured we shall have to stand a higher price than usual.

Oats.—There will be a good supply of this grain. Prices will not be much, if any, lower, for oats vary less in price than any other product of American soil. In my own locality more oats have been harvested than in any previous year that I remember. As the rye crop gave a good yield of grain, many farmers there will grind oats and rye together for stock feed. Thus we hope to save corn. The rye-straw crop is not as good as usual and reports indicate that the price ought to be good.

Potatoes.—This is a crop that I am greatly interested in. Our prices are regulated by shipments from the West. Mr. Dodge is a little in doubt concerning potatoes. He says there is an increased acreage, but this increase is mainly at the far West. The increase in the older States is small. The tendency is to take potato-growing across the Mississippi River. At this date, the prospects are not quite so good as they were at this time last year. Prices ought to be better than those of one year ago—I mean for late potatoes. I think this because most of the low condition is reported from the West. The crop at the South is reported very good. The Southern crop being early will be rushed into market and in good part cleared up before our late potatoes come in. That is the way it looks now, though foreign shipments may spoil it all.

Fruits.—The Washington reports state that the prospects for the apple-growing States of New York, Ohio, Michigan, Vermont, Pennsylvania and others are poor. New York reports only 59 per cent. of a full crop. Maine and Illinois seem to have the best crops while Michigan is far below her average. The R. N.-Y.'s reports of damage done by frosts give us an idea of what might be expected. It looks as though the farmers who have apples to sell this year are to be congratulated. Peach reports are very conflicting, with the chances apparently in favor of low prices. Grape prices promise to be above the average unless California "magnates" carry out their scheme of making such cheap railroad rates that they can flood the city with California grapes.

Market Truck.—No regular reports are given as to the condition of vegetables, except by a few local societies or clubs. From what I can learn I should say that Lima Beans will be in good demand at fair prices. One danger is that their season will be shorter than usual so that more of the crop must be brought in at one time. Sweet corn ought to find a somewhat readier sale than last year, but prices will not be much improved. A shortage of the crop in the canning districts of Maine is reported and this may make business somewhat more lively for canners who depend upon this market. Tomatoes promise to be very plentiful. Canners state that the supply of canned goods is already too large so that there will probably be less relief from this source than usual. The season seems to have been favorable for cabbage and low prices should rule.

Eggs are now bringing good prices and so are live fowls. Now is a good time to sell poultry. September will be a first-rate time to buy. Dairy goods are here in abundance and some specimens find very slow sale. Some commission men who, in former years have sent out men to buy butter from creameries, will be saved the expense this year, as they have no difficulty in securing all they want. This shows how rapidly the dairy business is growing. In another article I will try to tell more about the market and the marketmen.

TEXAS FEEDING EXPERIMENTS.—Bulletin No. 6 from the Texas Experiment Station.

The experiments recorded in this bulletin were conducted with a view to answering the following questions·

1. Is there any practicable method of sheltering range steers in winter feeding, and will it be profitable?

2. What feed stuffs that are obtainable in the State will give the best results in proportion to cost?

3. Can the common, unimproved Texas steer be fattened with profit?

These questions appear at first sight to be of local interest only, yet when we consider the fact that under the present systems of beef distribution we are all liable to be called upon to eat beef from Texas, we can see that anything that promises to improve the quality of that beef is of general interest. Texas feeders will be prompted to study the details of the experiments; the general public will be interested in the conclusions.

Director Gulley concludes that shelter for Texas cattle is necessary, and that dehorning is essential to make sheltering range cattle practicable. Silage forms an economical food. It can be made from corn, sorghum, or peavines. Cotton-seed hulls are also valuable. For the richer part of the ration, use boiled cotton seed, cotton-seed meal with some corn, rice meal or rice bran, in sections where they could be procured cheaply. This, it must be remembered, is for Texas. The cheapest and most fattening ration was found to be silage and boiled cotton seed; then followed cotton-seed meal and cotton-seed hulls; cotton-seed meal, cotton-seed hulls and silage; raw cotton seed and silage, and corn and hay at local prices. It was found that cattle fed on boiled cotton seed relish a considerable amount of salt. Some experiments were also made to determine the feeding value of sugar-cane bagasse. Analysis indicates a value for this bagasse not much below that of corn silage. Bagasse from the smaller sugar mills could doubtless be preserved in silos. A year ago the R. N.-Y. gave some facts regarding the feeding value of sorghum bagasse as it came from a northern mill. We shall have more to say about this later on. Under the head of "Suggestions to Feeders." Director Gulley has the following to say :

Two things are essential in fattening animals:

1. To keep the animal comfortable and quiet.
2. To induce him to eat the largest possible amount of nutritious food.

One is of little value without the other. To keep the cattle comfortable, shelter from rain is indispensable. Cattle fall off as rapidly during a cold, rainy spell in Texas with the temperature at the freezing point, or a little under as they do in Dakota with the temperature below zero.

Range cattle, as a rule, will not do their best under close confinement, *i. e.*, tied up by the head. They may be shut up in a building, but need room to move around.

Wild cattle must be handled quietly. *This point we wish to emphasize*, for it is entirely overlooked by too many cattlemen. A barking dog and a noisy, loud-mouthed man are two things that should never be permitted to enter a cattle feeding-pen. It should be remembered that when a naturally wild steer is struck with a whip, or disturbed in any way, he stops gaining weight for a time, and food consumed is a loss.

This is not a sentiment, but a business matter of working the animal machine to its full capacity. Dehorning seems to affect a wild steer somewhat as "throwing" affects the horse in the Rarey method of breaking colts. Then the head remaining sensitive for some time, wild steers are subdued and stand quietly together in a way that must be seen to be believed.

We are of the opinion that steers should be dehorned but a short time before shutting up to feed so that they may be fattened while their heads are somewhat tender.

NORTH CAROLINA EXPERIMENT STATION.—Bulletin 63 gives a report of a continuation of the tests of seeds, begun in 1888. The following deductions may be drawn from the experiments thus far conducted:—

1. Grass and clover seeds deteriorate very rapidly with age, and generally are not worth sowing after they are two years old.

2. That aged and deteriorated seeds are often sold by local store-keepers.

3. That farmers should test samples before purchasing seeds, and purchase directly from some reliable seed-grower, or from a local merchant who will guarantee the quality of his seed.

4. That a trustworthy standard of value for seeds, with laws, if necessary, to enforce its observance, is very badly needed.

Under the head of "Laboratory Notes" we are told that stable manure, in drying, loses but little of its ammonia. A pile of manure was exposed to a slow current of dry air, which was afterwards tested for ammonia. It was found that the amount taken from the manure by the air was inconsiderable. This matter was brought up during the R. N.-Y.'s recent visit to Cranbury, N. J. The practice there is to spread stable manure on the sod in August or whenever, during the summer, it can be hauled. Objection was made to this plan that the sun and air would "dry out" the ammonia. Farmers had not noticed such a process. The above recorded experiment, would indicate that the practice was reasonable. The sun, however, made the manure hard and cloddy, though its mulching effect on the sod was good.

DELAWARE EXPERIMENT STATION.—Bulletin 5 contains a paper on seed testing. The tests seem to have been conducted with a great deal of care. In one sample of Red Clover seed 9.18 per cent. of impurities was found. Among the weed seeds present were plantain, rag-weed, pig-weed, sorrel, dock and catnip. There were weed seeds enough in this sample to plant one seed every six inches in drills nine inches apart, supposing the usual amount of clover seed to be used per acre. Tests as to the vitality of seeds were also conducted. Prof. Chester does not seem to think that a difference of a few per cent. in the germination of seeds is of very much importance. He says that one pound of clover seed contains about 284,000 seeds. When we sow eight pounds, we get 2,272,000 seeds, giving 52 seeds to the square foot. In any ordinary clover field, he says, not more than three stools will be found on a square foot. It is probable therefore, that a good portion of the clover seed might fail to come up and yet leave enough for a seeding.

A SIGNIFICANT MOVEMENT.—This is the little title of a circular issued by representatives of the Farmers' Union, the State Grange and the Labor organizations of New York State. It appears that these representatives met at Rochester, July 3, and decided to issue this address to the tax-payers of the State. The address states, in substance, that, 10 years ago, the State debt was, in round numbers, $10,000,000 which is now substantially wiped out. Then the State taxes were $8,000,000. This year the legislature voted $12,000,000 taxes. The rate was then 2.6 mills on the dollar, now it is 3.52 mills. Personal property then paid one-seventh of the taxes, now it pays one-tenth. Then real estate was assessed at $2,376,000,000; now at $3,122,000,000. Then personal property was assessed at $364,000,000; now at $346,000,000, though any man of common sense knows it has rapidly *increased*. The farming lands of the State have decreased in value more than 25 per cent. Real estate in cities has increased in value and pays an unjust proportion of taxes, but owners recoup their taxes in increased rents. Whenever and wherever appropriations are made by those who pay no considerable portion of the taxes required to meet them, wasteful and extravagant expenditures may be expected, since no motives of economy restrain their taxing power.

The State Comptroller says: "I am sure that the actual value of the personal property of the people of the State *legally liable to taxation* exceeds that of real estate. That being so, the startling fact is apparent that we have within the State to-day *over* $2,500,000,000 of personal property that is not—but ought to be subject to taxation. * * It is apparent that the present result of taxing personal property is a travesty upon our taxing system which aims to be equal and just. A remedy is loudly demanded from the legislature."

The Governor has urged the passage of laws that would equalize taxation and each of the political parties has pledged itself to right the wrong. It is not yet righted. Untaxed capital has defeated every bill that has been introduced with this laudable end in view. The representatives who held this convention are getting tired of this business. So are we all, for that matter. This is what they have to say to the voters of the State.

"We therefore appeal to the manhood and self-interest of the tax-payers of the State and to the justice of all honorable and fair-minded men, to unite in the approaching election and choose a legislature that will restrict taxation to the legitimate needs of the State, equitably adjust the burden upon all the property liable to taxation, wipe out 'combines' and 'trusts' within its jurisdiction whose purposes are to increase the price of the necessaries and comforts of life, and especially destroy the 'publishers' combine,' which under present laws extorts exorbitant prices for the text-books used in our public schools. These indirect taxes are as oppressive and grievous as the direct taxes, and they affect a larger number of our people. To this end and for this purpose we earnestly recommend that steps be immediately taken to secure the nomination of candidates for the Assembly and Senate, in every elective district in the State, who are in favor of and will support the principles enunciated in this address. Party strength need not, and probably would not be affected by this movement. The question is simply whether our next legislature shall be chosen by the tax-payers of the State in their interest and behalf, or by political machinery in the interest of untaxed capital, to be manipulated and controlled by it." Choose ye which it shall be.

Many of the men who sign this address are known to the R. N.-Y. as thoughtful and honorable persons. We are glad they have spoken. We hope farmers will listen and act. The R. N.-Y. would like nothing better than to see this matter carried through. New York State local politicians don't approve of taking things out of the old groove. It is pretty hard in some places to elect a coroner unless he will promise to carry out his strict party principles even in his treatment of the dead, but this chance must not be neglected, even if the little party bosses are all upset. The "publishers combine" should be taken in hand first of all. Let us have cheaper and better school books.

The R. N.-Y. has not verified the figures given in the above statement. We believe, however, that the comparative statements of the assessed values of real and personal properties are fair. And the tendency among city and town people is to demand a further tax exemption for personal property. Within the past few weeks several papers of national reputation have used the statement of the N. Y. State Comptroller as an argument in favor of the complete exemption of personal property, giving as their main argument the difficulty experienced in assessing it properly. Such an exemption would throw the burden of taxation upon farm lands already over-taxed. It is in substance the Henry George theory over again. The farmers of N. Y. State, and in fact those of all the States are greatly interested in this question. The R. N.-Y. hopes that the next legislatures will show that this interest worked itself into a substantial form.

BUREAU OF EDUCATION.—Nos. 3, 4, 5, 6 and 7 of the publications of this department are issued from Washington. They deal with educational matters in Wisconsin, South Carolina, Georgia, Florida and North Carolina. The volumes dealing with the history of public education at the South are very interesting, particularly so to those who have studied the merits of the "Blair Educational Bill." There was a marked difference in the educational methods employed by the descendants of the Puritans on the one hand and the Cavaliers on the other. The Puritans founded a school and appointed a master one-half of whose duty was to teach and the other half to see that every child in the community came to school. As a result of this beginning the Northern States have always been strongly inclined towards compulsory education. The Cavalier sought the South. He had aristocratic ideas concerning the uses of education. He preferred the "academy" system of instruction where education could be bought by those who could afford it. The Puritan established the public school where the boy with a ragged jacket and patched trousers could put his tin cup into the fountain of knowledge. The Cavalier inaugurated the "pay" schools where money or pedigree divided the sheep from the goats. Up to the time of the war the South made little progress toward the establishment of public schools. Efforts were made at various times to begin the system, but the established academies and colleges never favored the plan. Private schools and tutors were quite popular. How any of the negroes ever learned to read is quite a mystery. After the war, every Southern State began a movement toward popular education. At the present time most of these States provide about 12 weeks free school during the year. The old "institutes" and academies are often run as "pay" schools for four months and as "free schools" for the threee months provided for by the State. During the "free" terms the teacher draws his money from the State while for the "pay" period he collects his money from parents. School money at the South is quite apt to "run out" early in the season. The writer taught for a short time in a Southern public school. He was paid in "school warrants" which could be turned into cash only at a discount of 20 per cent. offered by the local bank. The Southern public school system is quite imperfect yet, but the fact must be remembered that it has much to fight against, historical precedent, local prejudice and the influence of the friends of the old academies are against it. Still, it will conquer in time and work a vast change in Southern society and prospects. It is an element for good.

AWFUL FATE OF AN AUSTRALIAN MAIDEN.

There was a young woman of Sandhurst
Who would face any peril a man durst;
She was braver than that,
For, although rather fat,
Yet she squeezed in her waist till her band burst. —Sydney Bulletin.

AN EARLY CROP.—Neighbor: "Well, Giggings, what are you raising?" Amateur gardener, sadly: "Blisters."—*Toronto Empire.*

THERE is one thing that the invincible Western cyclone has never yet succeeded in lifting, and that is a mortgage.—*Burlington Free Press.*

TEACHER: "Inanimate objects belong to the neuter gender. What gender is an egg?" Tommy: "Can't tell till it's hatched out."—*Texas Siftings.*

A, SOMEWHAT illiterate: "I read something in a paper about idiots. Are they human beings?" B: "Certainly, they are human beings like yourself?"—*Siftings.*

"I AM like a tree," he observed, as the clock struck 11. "I am rooted at your side." "Yes, but you never leave, do you?" And then he "put forth."—*Harper's Bazar.*

WAITER (reminiscencing with old customer): "Time flies, sah." Old customer (removing fly from the cream): "Yes; time flies were gone."—*Orange Judd Farmer.*

YOUNG SLIPJACK: "Ah, I would like to cross that field; do you think—Ah—that cow would hurt me?" Farmer: "Did you ever hear of a cow hurtin' a calf?"—*Grange News.*

"I'M so indignant that I cannot properly express myself!" cried the speaker. "Then put a stamp on yourself and go by mail," was the unsympathetic response.—*Harper's Bazar.*

OLD LADY: "I believe the Cape May boat leaves this pier, does it not?" Pierman: "Yes, marm; it leaves it every trip. Never knew it to take it over with it yet, and I've been here getting on for 40 year come this June."—*Tid-Bit.*

QUITE a little fellow found one afternoon that the older pupils in the school that he attended were going off for a long tramp in the woods. He asked to be allowed to go and was told he was too small, but he begged so earnestly and was sure he would not be tired that he was finally given permission to go. He held out bravely though the last two miles were almost too much for him. "I am not tired," he said, "but if I only could take off my legs and carry them under my arms a little while I should be so glad!"—*Youth's Companion.*

STRAWBERRIES

THE MOST PROMISING OF THE NEW VARIETIES.

THOSE FOUND WANTING.

THE STRAWBERRY SEASON OF 1889.

SOME OF THE MORE RECENT STRAWBERRIES.

PRES. T. T. LYON.

BUBACH No. 5 (pistillate) and JESSIE (bisexual) have now pretty fully established a reputation as very large and productive varieties, of medium season, and of not more than medium quality. High culture, however, is indispensable, to even fairly maintain the size of the later specimens; while several of the older and medium-sized varieties still equal and perhaps even surpass them in actual productiveness, as well as in quality.

GANDY (b) and possibly OHIO, (p) very nearly approach the above in size, and may quite possibly rival if not even supersede Kentucky and Glendale as late varieties.

HAVERLAND (p) seems quite likely to rival and even supersede Crescent as a market variety, which would be a gain in point of quality also.

LIDA (p) is of fine size, abundant vigor, and enormously productive, if, (as is indispensable) it is given rich soil, and high culture; otherwise the later berries are sure to be abortive or imperfect.

SUMMIT (p) is only moderately vigorous, and fairly productive. Its fruits, even though enormously large, are always perfect in form — never coxcombed.

PEARL (b) is very vigorous and productive. Although little above medium in size, its quality is good. It promises to assume a high position among market varieties.

GOLD (p) is only of moderate vigor. Its quality is very good. It is a very desirable amateur or family variety.

BURT (b) although of only medium size, possesses valuable qualities of both plant and fruit; which will, quite probably, render it popular as a market variety.

BOMBA (b) and MAMMOTH (b), like Jessie, produce a few very large first fruits; but rich soil and high culture are indispensable to the size of the later specimens. Whether these can be depended upon for such a purpose, I regard as uncertain.

CLOUD (p), although only planted late in August last, shows very satisfactory vigor of plant; but a longer trial is needed to decide as to its productiveness.

CLARA (b) received for trial from Cleveland, Ohio, late last autumn, has been allowed to mature a few fruits, and so far promises well.

PARKER EARLE (b) was also received late last autumn, from Texas, for trial. It gives indications of great vigor, productiveness, and superior quality—a combination of good qualities hardly to be anticipated in a variety so widely removed from its place of nativity.

DEW (b), an enormously large and wonderfully vigorous, Michigan seedling, Mrs. Cleveland (p), Ohio Centennial (p), Townsend's No 3 (b) and Townsend's No. 19 (p) all received from Ohio, for trial; also Little's No. 10 (b) and Loudon's No. 15 (b) received for trial, the present season, from Ontario, are all developing desirable qualities of plant or fruit, or both, and the same is true of a trial variety (p) received from Illinois, which it is proposed, if found valuable, to name Lady Rusk.

WONDERFUL (p), Norman (b), Pineapple (b), Miami, (nearly p), Louise (b), Hampden (p), and Crawford (b), were only planted the present season, and although several of them manifest great vigor and some also afford decided indications of productiveness, it is not deemed proper to speak of their performances upon so short an acquaintance.

A variety which proves to be nearly pistillate, was received last season for trial from Minnesota, and it has since been named Martha. The plant is very healthy and vigorous, with substantial, dark-green foliage and medium-sized fruit, of very good quality. I am not informed whether or not it is yet offered for sale.

MOORE'S PROLIFIC (b), is a recent variety said to have originated in Eaton County, Michigan. Grown in parallel, matted rows, alongside of Jessie, and given the same treatment, it proves equally vigorous and productive. The size of the fruit is the same, although it is somewhat different in form. In quality I deem the Moore somewhat superior, though but slightly so. The variety has now been grown several years in Eaton County; and for the last two years at this place. I am not aware that it has been at all advertised.

South Haven, Mich. SECT'Y E. WILLIAMS.

The PEARL and JESSIE have given me very good satisfaction during the past very unfavorable season for this fruit, and I have no reason to modify the impressions formed of them last season. They are early, ripening within a day or two of each other. The former I like the better, it is so handsome, perfect in shape, always well developed, ripens evenly, slightly necked so that the calyx is easily removed; the quality is very good, and it is large enough to meet all reasonable demands. The plants are vigorous and fairly productive. The Jessie is quite as vigorous and productive. The first berries are perhaps a little larger, with too much tendency to ripen unevenly. This it probably inherits from the Sharpless, as well as its inability to hold its flavor after reaching maturity. The Sharpless loses its fresh, agreeable flavor very soon after becoming ripe. In fact, it is really better to my taste before it is fully ripe than afterwards, and this tendency to lose character, is in my experience, the chief fault of the Jessie. I hear very conflicting and unfavorable accounts of its behavior in other localities. This is not at all strange. The soil in which it originated, I am told, is a deep stiff clay in which it withstood protracted drought unharmed, conditions not to be found in many localities this season, and the sooner the idea is abandoned among originators, disseminators and growers, that the ideal strawberry has yet been produced that will adapt itself equally well to all conditions of soil, climate and culture, the better it will be for all concerned.

BELMONT seems to possess all the virtues and few of the vices of the Sharpless, save unproductiveness and uneven ripening, and will take its place with me another season at least.

BURT, sent out last season to take the place of the Wilson, does not show the vigor and productivenss characteristic of that variety; but it is far better, in my estimation, on my soil. The plant is healthy; the fruit of fair size and handsome, rather acid without liberal additions of sugar which all strawberries are apt to receive, no matter how much nature may have placed in their composition.

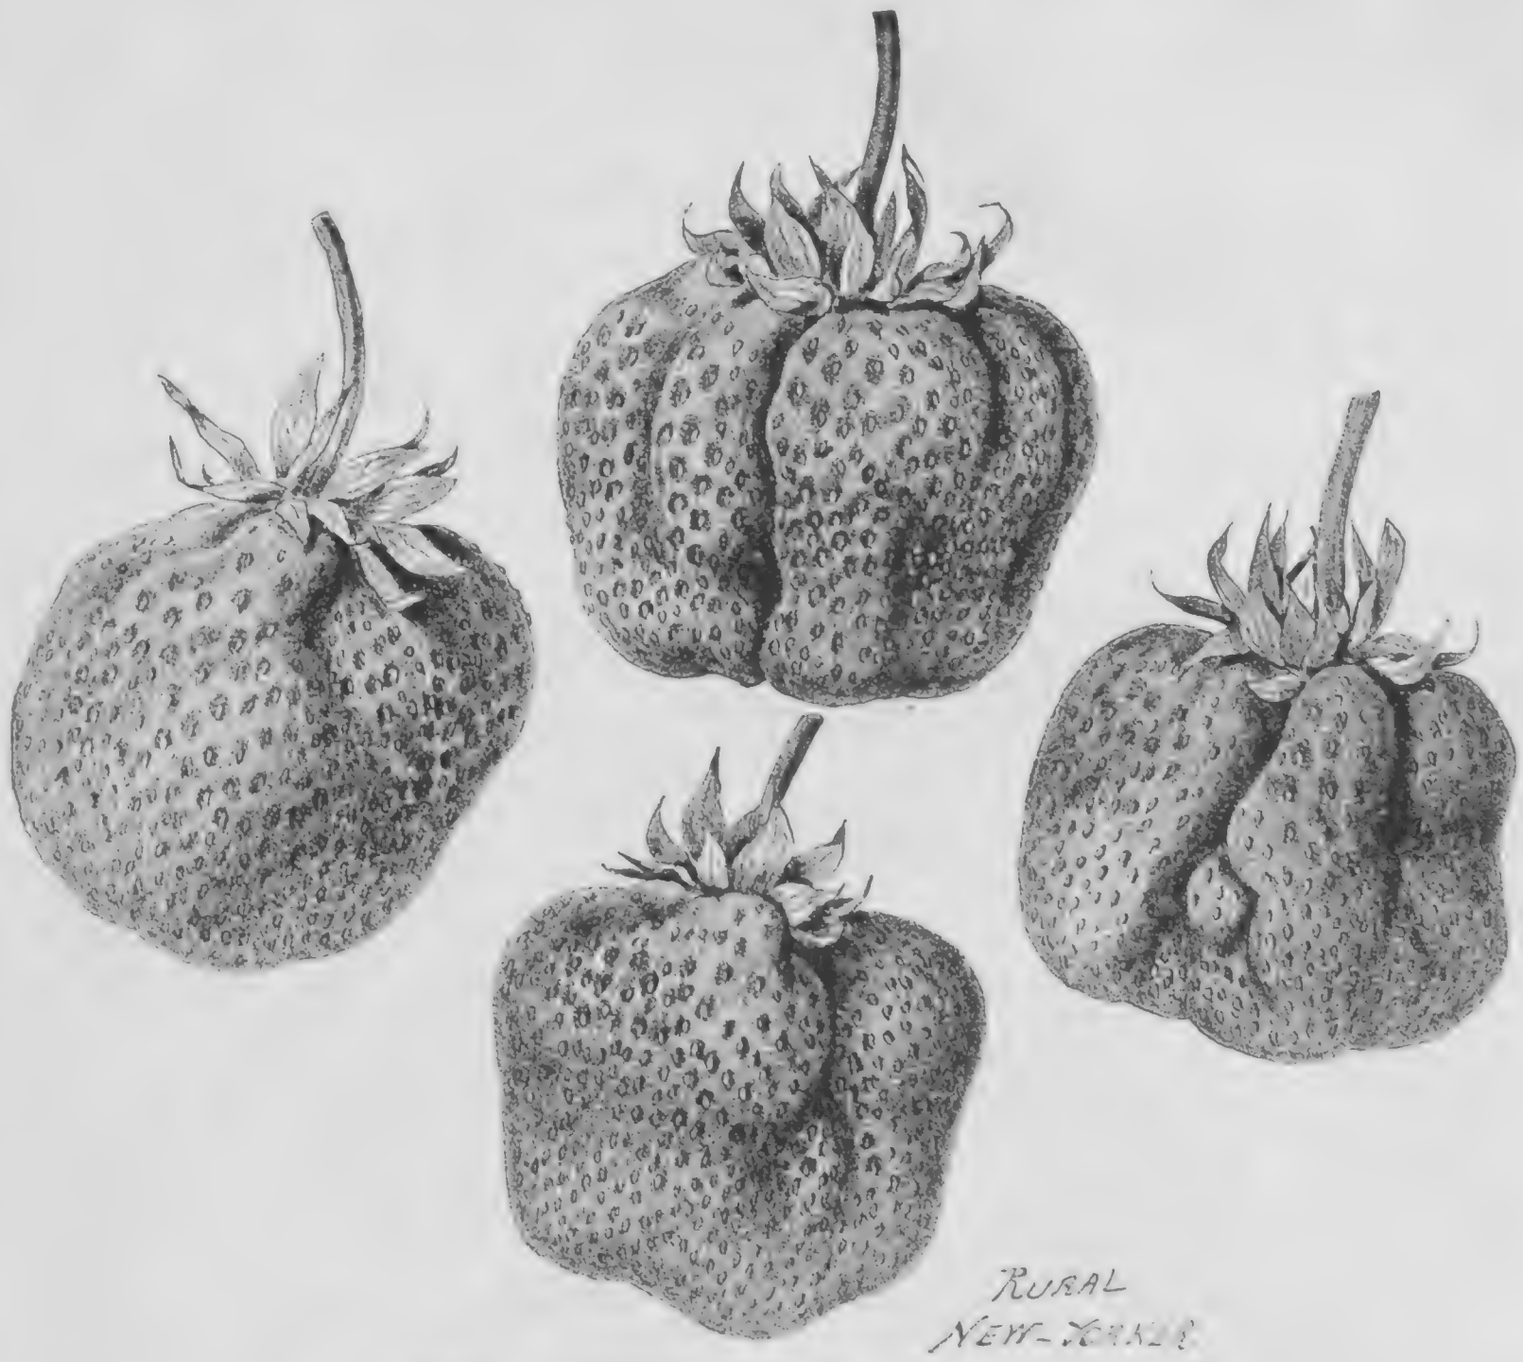
OHIO, sent me last season as new, is the old Champion (Windsor Chief) rechristened or reproduced, and its quality is well expressed by J. B. Olcott of Connecticut, who, in speaking of another variety, said it would flavor more sugar than any variety he knew of.

PRINCE (DURAND'S SUPERB) in quality is the best berry I have, though not quite so productive as I would wish; but as my primary object in growing strawberries is to eat them, I can afford to grow a few of them for this purpose.

JERSEY QUEEN, its twin-sister, is more vigorous and productive as well as larger, and more acid.

BUBACH is the most promising of the newer varieties, fruiting with me this season for the first time. It is early, large, bright-colored, handsome, vigorous and productive and ripens evenly — all valuable traits in any berry. The quality is hardly up to that of some of the others, but still I think it will do to plant more of it.

WARFIELD AND HAVERLAND are also well

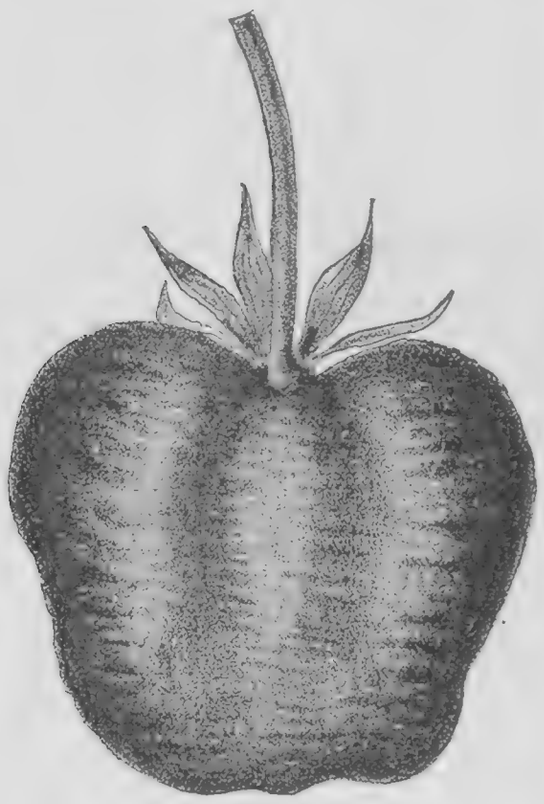


THE MARY STRAWBERRY. From Nature. Fig 196.

spoken of elsewhere, but these I have not yet fruited: in fact, new varieties multiply so fast that I cannot keep pace with the procession.

The great trouble attending my strawberry culture is the prevalence of brown rust (blight) and rot which run riot in such an excessively wet season as the past has been, and in future I must confine myself to those varieties that seem to possess constitutional vigor sufficient to resist most successfully the attacks of the fungus. That some varieties are more susceptible to this disease than others is, beyond question, a fact. While age and long cultivation of a variety may enfeeble and impair its vitality and increase its liability to an attack of this fungus, it is also very evident that some new varieties fresh from the hands of the originators, are extremely susceptible in this direction, thus rendering absolutely worthless whatever other good qualities they may possess, in regions where this malady prevails. This disease-resisting feature of constitutional vigor should be well looked after by originators of new varieties. It is on account of this fungus that I am compelled to abandon Sharpless, Davis, Jewell, Downing, Gold, Dewey, Acme, Cohanzick and scores of seedlings. Some of the above have little merit with me at their best and this fungus renders them worthless. I part with Downing more reluctantly than with all the rest. Most of those I retain are slightly subject to this disease, but they are the least affected so far. If in the future this tendency increases, they too must go.

Among all our new varieties there are many good ones, but the ideal berry has got to come so that there is plenty of room for originators yet. We want a berry as large as the Sharpless, of even shape, good color and flavor that will stand at least two days without spoiling, and stand shipping from Florida to Chicago.



MARY. Half-section. Fig. 197.

It must be as productive as the Haverland with a perfect blossom, so we have a great improvement to make yet before all these things are reached. With all due deference to the shipping qualities desired, I hope, for the sake of local growers, such a variety will never be obtained. Those long-distance-shipping berries have ruined the business for thousands of local growers by flooding the markets and sending prices down below a living profit and disgusting consumers with the utter worthlessness of much of the decayed fruit offered in our markets early in the season.

The reader of these hastily-written notes will bear in mind that they are based on a home consumption view only, without any reference to shipping or marketing purposes. I believe that strawberries were never designed by the Creator to be consumed hundreds of miles from the place of their growth. To get the most satisfaction out of this ambrosial fruit, they should be consumed within 36 hours, at farthest, after being picked and transportation should be confined to local markets. If it were so, growers would realize living prices, consumers would be better served and our markets would be rid of the decaying, unwholesome trash that constantly tends to force prices below a living profit. It is strange that berry-growers will persist year after year in spending their time and labor in producing crops in order that transportation companies and commission merchants may absorb all the proceeds. No other business or class of men could or would stand it; but I suppose as some drop out, enough inexperienced greenhorns stand ready to rush in and fill their places, which keeps the ranks full.

Montclair, N. J.

EXPERIENCE WITH THE NEWER STRAWBERRIES.

STATE POMOLOGIST P. M. AUGUR.

JESSIE: Very good; fairly productive.

BUBACH No. 5: A most decided acquisition. A good, medium-early market berry.

GOLD: A very choice berry for family use: not so vigorous or hardy as desirable for a market berry. It needs the best culture and protection.

HAVERLAND is too much like the Crescent to meet our demand, yet it has some strong points.

JEWELL: I have always been called upon to send out heavy plants, and with me the Jewells grow remarkably heavy; but the nearer fruitage a plant comes the less value for propagation; hence a young plant struck in October is of far more value for immediate multiplication than one struck in July and full of fruit germs. In other words, the smaller plants make more runners than extremely heavy ones. These points are important to be known, as my orders for this variety increase year by year. The Jewell needs single-row or hill culture, or else what we call the triple row. With us, for size, beauty and productiveness it surpasses the Jessie, Bubach and all others, as we have most convincing testimony.

THE MIDDLEFIELD.—P. M. Augur & Sons' No. 70. This is a most promising variety. Like the Jewell, it is pistillate. Unlike the Jewell, it makes runners profusely. It has a peculiarly corrugated heavy leaf. The plant is fairly hardy with abundant foliage. The berry is of excellent quality, medium to large, of a dark, glossy, crimson, with roundish, conical golden seeds evenly distributed. The fruit is very uniform in size and form, attractive to the eye and keeps well.

THE CARDINAL.—P. M. Augur's B. No. 411. This is the only variety saved out of a batch of 500. The plant is one of exceptional vigor and excellence. The berry is very large, somewhat irregular; color scarlet; quality good. It is well adapted for family use or a near market, but does not stand up like our No. 70; neither is it as high-flavored; still it stood ahead of all bisexuals on our ground for health, size and productiveness this year.

THE PINEAPPLE is praised as a very choice variety of large size and fine quality, but I fear it is of too light color to be attractive in market.

THE YALE is a Connecticut seedling in the hands of S. Hoyt's Sons of New Canaan. The plant is vigorous and productive. Color dark crimson; quality very good, and in ripening it is quite late. I regard it as a promising large, late variety. We have many other new candidates from various sources, of which it is too early to speak.

Middlefield, Conn.

THE NEWER VARIETIES OF STRAWBERRIES THAT ARE WORTHY OF COMMENDATION.

SEC'Y M. CRAWFORD.

THERE are but few such, and not one without some weakness. The Jessie, Bubach, Warfield, Pearl and Haverland come nearer to perfection than any others that are as well tested.

VALERIAN. Fig 198.

JESSIE has no weak point here, except that its blossoms are easily killed by frost. A few years ago I never expected to see as fine a berry; but now I am prepared to see even a better one.

BUBACH is the largest berry that bears as heavy a crop. The plant is faultless. The blossom is pistillate, and quite hardy. Some of the berries are divided by a suture that detracts somewhat from their fine appearance. They ripen evenly, and are of a good color. The quality is good, but not superior. The berry is not firm enough for a distant market, and its skin is too tender for continued wet weather. It is *the* berry for a near market. We sold bushels of this variety the past season, that ran from 27 to 30 to the quart.

WARFIELD will doubtless be placed at the head of the list by a great many, and this is where it belongs if one wants to ship his berries. For healthy, vigorous growth and great productiveness, it is not surpassed. It is among the first to ripen, and among the last to yield a good picking. It is about one half larger than the Crescent, and maintains its size much better than that variety. It is also superior to it in form, color, quality and firmness.

PEARL is a strong grower and a good bearer. It has a perfect blossom and is one of the first to ripen. The berries are very beautiful—long and conical with a slight neck. It is of the best quality—good even before it is fully ripe. It is of large size all through the season.

HAVERLAND is a most luxuriant grower and immensely productive. It is quite early and it matures all its fruit. It is of large size rather long, and never mis-shapen. Its fruit-stalks are weak so that the berries lie on the ground. The quality is only moderately good, and hardly that in a wet time. During the past season I fruited a large number of new varieties received from different parts of the country and of these I find the following to be very fine on my place:

IVANHOE, from southern Ohio, has a perfectly healthy, vigorous plant, and bears a very heavy crop of large, fine-looking berries. It has fruited twice with me, and I consider it a variety of great promise.

MARTHA, from Minnesota, has dark-green, healthy foliage, and is very productive. The fruit resembles the Wilson, but is larger.

LITTLE'S No. 4, from Canada, was the finest berry, all things considered, that I fruited this season. The plant is strong and vigorous, has a perfect blossom, and continues in bloom a very long time. The fruit is of great size, usually of good form, bright red and of good quality. I think it is the most productive very large berry I have seen, and it yields fine berries after most others are gone.

LOUDON'S 15 has fruited here three years. The plant is perfect, never having shown a single weakness. The blossom is hermaphrodite. The fruit is produced on large spreading trusses so that each berry may be picked without touching any other. The fruit is large, round to conical, with a neck. It is quite firm, bright red, and of superior flavor.

CARDINAL and AUGUR'S No. 70, from Ct., are two very promising varieties, and will doubtless be heard from hereafter. They are of great size, and the plants have developed no weakness as yet.

Cuyahoga Falls, O.

STRAWBERRY NOTES.

FROM C. L. JONES.

I have in cultivation only four varieties, viz: Prince, Gypsy, Jessie and Pearl. All are good on my ground save Jessie. Prince for late, and Gypsy for early are my standard sorts and are doing well. Pearl is very promising.

Newark, N. J.

FROM L. LAWRENCE.

The past season has been most discouraging. The strawberry crop in this vicinity has been very light, owing partly to the late frost and partly to a lack of fruit buds; while the almost daily rains during the picking season injured the quality. We have, however, watched with pleasure the new varieties The Jessies behaved nobly. They were loaded with fruit. The plants bore three times the amount of fruit borne by the Ontario. I never saw so high a proportion of large berries before. The soil was but moderately good. We are highly pleased with it.

We are charmed with the Crawford also. The plants and berries were grand. My opinion is that it is the berry to succeed the old Cumberland. It has all the beauty of size and shape of that variety while it is of better color and quality.

Barnesville, O.

FROM JNO. F. BEAVER.

I had one Belmont that measured 8¾ inches in circumference. I think I had the grandest show on about 400 plants of the Crawford, that has ever been seen in this county. The Summits were immense, but the Crawfords were the favorites. The largest measured seven inches.

Dayton, O.

FROM M. J. GRAHAM.

My plants of the newer kinds were set early in April, in new, rich soil that would produce 100 bushels of corn per acre. About May 10, myriads of chinch bugs attacked them and sapped the stems until the leaves dried up. I applied a heavy dressing of dry unleached ashes, scattered broadcast over the ground and plants, which drove them away. Thorough cultivation, followed by copious rains, caused the plants to take on new life.

Monmouth was very slender when planted, but has proven stocky, and the runners are nearly as heavy as those of Bubach.

On the morning of May 31 we had 10 degrees of frost which destroyed nearly al of the strawberry crop. Bubach produced some magnificent berries, fully as large as the pictures. Mammoth stands high with me, being *double* the size of Jessie and five times as productive. In fact with Mammoth and Bubach planted side by side, I see nothing farther to be desired in the way of large berries. Cornelia was quite productive and the berries of fine form and flavor.

Adel, Iowa.

FROM W. H. HOLMES.

My Jessies and Bubachs did splendidly this season. Haverland is one of my most promising varieties. Lida and Bomba are extra, but are scanty in foliage. No spring-set plants of twelve new kinds equal Cloud and Stayman in vigor of growth. These are followed closely by Crawford, Eureka, Miami, Burpee's Louise and Pearl.

Davenport, Iowa.

Notes from the Rural Grounds.

THE NEWER STRAWBERRIES.

WITH very few and generally unimportant exceptions, the R. N.-Y. has from year to year made its reports upon the new strawberries as they have been announced and tried here. When these reports please the introducers the R. N.-Y. is often complimented and thanked. But it deserves neither compliments nor thanks. When these reports speak disparagingly of the new variety, the introducer is often displeased. We have a note before us now: "I demand that you destroy all the —— plants I sent you and that you never again mention its name in your paper." This is equally unjust. The R. N.-Y. does not deserve censure in this case any more than it deserved praise in the other. The new variety was fairly tried beside a hundred others and found wanting. What are such trials made for? It is manifestly to the R. N.-Y.'s interest to give praise where praise is due. It is manifestly its duty to tell the truth freely when a variety is found to be worthless or inferior. It should always be borne in mind that the fact that a given kind of strawberry does not or does thrive here is but circumstantial evidence that it will succeed or fail elsewhere.

MARY.—Received from H. H. Alley, Hilton, N. J., July 25, 1888. Three plants only. No suckers. Plants fairly vigorous and productive. Berries all large. Peduncles not very strong. It begins to ripen in mid-season continuing to late season. The color is a bright red, rather than either "scarlet" or "crimson," the two adjectives so generally used in defining the color of strawberries. Skin glossy—seeds not deeply imbedded. Firm and regular for so large a berry. In these respects it may well be compared to the Downing, though the angular shape is more that of the Sharpless.

In early July Mr. Alley, who is a straightforward, hard-working man, brought to the office of the R. N.-Y. a quart or more of berries which he had that day picked from his own vines. The illustration Fig. 196 accurately shows the average as regards size and shape. Mr. Alley said that he picked 21 of the best and found that they weighed one pound 12 ounces. The seed of the Mary was sown three years ago. Champion was the female and Great American the male parent. The past season, Mr. Alley says, the Mary was the most productive of 500 different kinds. The quality is of a strawberry acidity not far from that of the Wilson. The flower is pistillate as we remember.

HAMPDEN (nearly pistillate) from J. W. Adams, Springfield, Mass. Another season required.

HAVERLAND from C. A. Green, Rochester, N. Y. Conical shape often as if two berries were joined in the middle. Early, not very firm, medium in size, ovate-conical, quite regular, fair quality, scarlet, mcderataly productive, peduncles weak. Another season required.

GANDY is a desirable late strawberry. Bisexual.

ENHANCE proves this season, as in seasons past, one of the most productive berries ever raised here. Quality poor, shape very irregular, size very large. Its season is from medium to late. It is bisexual. Vines very hardy and vigorous, often 18 inches high. Henry Young, Ada, Ohio.

LIDA. There is nothing to add to previous reports. Not desirable here.

BUBACH has scarcely sustained the reputation it has earned. The wet season did not suit it.

ONTARIO. Sharpless preferred.

EUREKA and CLARA both from the Cleveland Nursery Co., Ohio, will need another season. The first is nearly pistillate, the other bisexual.

CRAWFORD (b) has borne abundantly and a wet season agrees with it here. Vines not vigorous.

"SHARPLESS UPON JESSIE" (bisexual).—Plants set May '88 from Jerry Dutter, Angola, Md. Large leaves, vigorous plants. Long peduncles, rather slender. Quality good for so large a berry, better than that of Sharpless, and the vines are rather more productive. Heart-shape, often broad and flattened at the tip. Medium red, firm. Berries of the largest size. Vigorous foliage.

MINEOLA (b) from N. Hallock, Creedmoor, Long Island, May, '88. Season medium to late. Vines low and not very vigorous. Oblate-round, to broadly heart-shape. Firm, fine quality, quite productive.

LOUISE.—Plants received through W. Atlee Burpee & Company, Philadelphia, Pa., June 15, '88. Originated with N. Hallock. Bisexual. Fairly vigorous vines. Season medium to late, later than Mineola. Heart-shape, inclined to conical. Foliage vigorous. Color light to medium red. Firm. Excellent quality. June 16, we find the following additional note: Fine vines, berry averages large. It is largest in the middle, tapering to tip and stem. Light red, white like the Parker Earle before ripening. Quality excellent; quite prolific.

PEARL, received from E. & J. C. Williams, Montclair, N. J., April 1st. Vigorous vines. (b) Large berries, fine shape, ovate-conical.

STANDARD, from J. B. Campbell, North Reading, Mass., April 30. Nearly pistillate. Quality good, color light red.

VIOLA from S. K. Kramer, Gahanna, Franklin County, O., April 30. (b) Another season required.

WABASH, received from J. A. Foote, Terre Haute, Ind., in September of 1887. There is nothing remarkable about this variety.

YALE from S. Hoyt's Sons, New Canaan Conn., received September 12, 1888. Nearly pistillate. Medium to late. Foliage good. Berries from heart-shape to roundish, and quite regularly so. Quality good, quite firm. The color is a rather dull red later in the season. It does not succeed very well here as at present judged.

BELMONT will be rejected as unproductive.

Floricultural.

YUCCAS ON A CALIFORNIA FARM.

SOME of the finest species of yuccas in the world grow on the deserts of Arizona and New Mexico. One of the best is a native of the Mojave region in southern California. This species—Y. baccata—lives to a great age, and reaches a size that entitles it to be called a tree. It begins to bloom when quite small, and is very ornamental. The illustration Fig. 199 shows a portion of a row of 15-year-old yuccas, Y. baccata and Y. Whipplei, in bloom in the nurseries of James Shinn, near Niles, Alameda County, with Mr. Shinn, who is one of the oldest and best known horticulturists on the Pacific Coast, standing by one of the flower stalks. The stalks are 10 and 12 feet in hight, and the masses of large fragrant, bell-shaped flowers are very attractive. In the back-ground are groups of Australian Eucalypti, and the Coast Range foothills.

YUCCAS ON A CALIFORNIA FARM. From Nature. Fig. 199.

Rural Topics.

VALERIAN ROOT AS A CASH CROP.

In collecting the notes on "The Cash Crops" which were printed some weeks ago, the R. N.-Y. learned from E. A. Fassett, a subscriber at Hancock, Vermont, that farmers in that neighborhood found considerable profit in producing valerian root. As valerian culture is rather a new enterprise to most of our readers, we have collected a few facts concerning the culture, handling and sale of the root. A picture of the stem and flower is given at Fig. 198, in which a, b and c show the seed at different stages of its development. The cultivation of this plant at Hancock seems to be a local enterprise. We have not learned of any other section where it is cultivated to any extent.

Valerian root is quite largely used in medicine as an antispasmodic. It is impossible to get at the exact amount imported or used in this country. McKesson & Robbins, leading wholesale druggists of this city, estimate the imports of valerian at 25,000 pounds yearly. They do not think the consumption is increasing. They further state that the imported root can be had down here for about five and 5½ cents per pound. A great many consumers will use only the imported article. Thus it may be seen that the market may easily be overstocked. Still the production of the root provides a profitable business for a few localities.

FROM E. A. FASSETT.

This question was asked me last fall: "Why don't we see anything in agricultural papers about valerian?" The question was asked by a farmer who had raised valerian for 30 years. I don't think he has failed to grow a crop any year in that time. He used to be poor; now he is well off. He is one among several in this section who raise valerian with good results. I suppose the reason why nothing has been said about the business is because we farmers are not writers. We do the farming, and learned men must do the writing. The men who raise the largest crops often couldn't write about them if they tried.

Valerian culture was first introduced in this section by Dr. Wm. Huntington of Rochester, Vt., about 30 years ago. He has been a dealer in valerian in this section ever since. Tons of it have been raised here yearly. It is the staple article for cash for rich and poor. After it has been once started, there is no expense in raising it. As roots are left in the ground for seed, one doesn't have to buy any in the spring, and it doesn't cost anything to winter it. After the ground is thoroughly enriched and cultivated, we get big crops. One of my neighbors claimed to have raised 2,200 pounds, two years ago, from a little over an acre; but let us put the average yield at 1,000 pounds per acre.

After the ground has been thoroughly prepared, it is furrowed out two feet apart. The roots are plowed out of the ground, where they were left the fall before for seed, and separated by cutting the clusters of roots apart. Then they are dropped into the furrows and covered. The plot must be thoroughly cultivated and kept free from weeds. The crop must be got in as early in spring and left as late in fall as possible to get a heavy yield. In the fall the crop is plowed out and after the earth has been shaken off, it is carried to the dry-house to be cut apart by girls. Then it is washed, and dried in the same way as hops and packed in barrels. To wash valerian, take the boards 10 feet long and make a box of the desired width, and place it in a brook. Have it tight enough to hold all the water needed and still loose enough for the waste water to pass off. Handle with dung forks.

Hancock, Vt.

FROM C. DOWDELL.

I have grown valerian 24 years; my best crop was 2,400 pounds, and the poorest 900 pounds. I like a clay loam, with plenty of good rotten barn-yard manure. Plant in the spring as early as possible. Manure heavily; plow and harrow the same as for corn. The sets are obtained in the early spring, from some grower, as they are left in the ground all winter. For cultivation, hand-hoeing and fingers are used for weeding, as the crop is a very slow grower for the first three months. In spring the seed has to be dug and all the dirt that can be taken out in the field is shaken off, and the roots are taken to a building used for that purpose and there women pick out any foul weeds and cut up the cores and trim off all green tops. Then the seed is ready to be taken to the field and planted. In the late fall what is intended for market is at first treated in the same way as the seed. After it has been cut by the women, it is taken to a tank through which a large stream of water is running and there it is washed by men until it is perfectly clean; then taken to a drying kiln and dried as much as possible. It is then packed into barrels and is ready for sale. We sell to wholesale druggists and manufacturers of patent medicines. I have sold it here for 15 cents per pound, but of late years it sells for eight to 10 cents.

Hancock, Vt.

I MAY say a word about protecting cattle and horses from the ravages of flies in summer. I apply on my horses that are at work in the field plowing and mowing, crude petroleum. I buy it by the barrel. It is applied with a sponge on the legs and belly. It is harmless and will not hurt anything. F. P. Q.

Dairy Husbandry.

KEEPING MILK RECORDS.

PROF. C. S. PLUMB.

Object of the record; easily kept by a careful milker; a specimen special record; a general one; advantages of the practice.

FOR six years I have kept milk records, because I thought it a matter of business importance. Could I surely estimate by guessing as to whether all our cows gave us a profit or not? A cow that will not yield a profit has no business on our farm. A big udder is often deceptive. A big appetite may make more manure than milk. A big pail of milk for the first of the season may average a small one over eight months after calving; and a big pedigree may amount to nothing. Hence we ought to resort to the scales, for we may guess wide of the mark.

Scales may be obtained at from 25 cents upwards, so the question of expense in this direction is inconsiderable. Some will say that it takes too much time to weigh each milking, and record it, but this is not a good excuse, as the milk of one cow can be weighed and recorded in one minute. Further, men who do careful, painstaking work, always take time to do it. A milker should be neat in habit and careful in work, else he is not fit to draw milk from a cow. Such a person is always glad to keep a careful watch of the way the cows are doing. I have always made it a point to get as intelligent and capable a man for caring for the milch cows as I could secure for the money and have usually paid him a little higher wages than to the other hands.

The milk is weighed in the pail, on platform scales, the latter standing conveniently in a closet, and weighing to one-fourth ounce. As soon as the weight of the milk of each cow is taken, it is transferred to a slate opposite the name of the cow milked. The figures on this list are later transferred to a paper arranged on the following plan. It is ruled and arranged so as to serve for binding. Thus we preserve the records for a series of years, and have them easily accessible. Below the tabular matter, on a margin of three-fourths of an inch, are noted the character and amount of the feed of the cows In the table the names are arranged alphabetically for convenience. I copy from the June milk record of the University Farm, in pounds and ounces, the yield of three cows, for the month, to illustrate the system, and to show the difference in productiveness of milk. Aaggie, a Holstein-Friesian, calved in November, Iuka, a Jersey, in October, and Lizzie, a grade Short-horn in November. There is no intention to make an unfavorable comparison of breed, it being simply a matter of cow, these figures being used as the only ones available in cases where the cows calved nearly at the same time.

MILK YIELDS: UNIVERSITY OF TENNESSEE FARM.

1889.	AAGGIE.		IUKA.		LIZZIE.

" 30	17—15	16— 8	7— 9	7—..	3— 7	3—..
Yield	550— 1	533— 4	230— 1	220— 6	158— 8	163— 4
Total per month	1,083— 5		450— 7		321—12	
Total to date from last calving	7,484—13		3,742— 8		3,542—10	

It will be noted that the yields of morning and evening milkings, are kept separate, and combined at the bottom of the columns into the total for the month. In addition to this, in order to know how much milk each cow is giving, the total amount is kept up from month to month. Lizzie stopped giving milk early in July, but she has produced enough to yield a small profit. Iuka will continue to give a good flow of milk till calving in October, and the same will be the case with Aaggie; hence both of these animals will make much better showings than Lizzie.

In addition to the above form of table, which is filed away each month, I have a form after the style below, containing a monthly record of all the cows in milk on the farm, which I have handy in the pocket or on my desk, for reference, in order to note at a glance what the animals are doing, for comparison:

TOTAL MONTHLY MILK YIELDS OF COWS.

1888.	No. 1	No. 2	No. 3	No. 4	No. 5.
Aug.	800	1,000	350	250	100
Sept	900	1,000	500	241	800
Oct.	910	1,150	525	190	980
Nov.	860	1,160	540	183	999
Dec.	840	1,076	500	150	975
1889.					
Jan.	800	1,000	423	100	960
Feb.	760	960	375	65	800

At a glance almost, one gets a good idea of what the cows have done and are doing. All of the figures in both tables represent pounds. I have presented the facts above, as suggestive to others, but I know from personal experience that the method is entirely practical and business-like. In closing, I would say that the three animals above referred to have been soiled under the same conditions during the entire season. A record is kept of all the food eaten by each animal.

Knoxville, Tenn.

DAIRY NOTES FROM A DAIRY RANCH.

NO. II.

DAIRYING ALL THE YEAR.

Winter dairying a comparatively new business; present dairy appliances render it easy; advantages of it; an unsatisfactory substitute; low prices for milk and high prices for butter demoralize a creamery and its patrons; a cheap ice-house.

TWENTY years ago we never heard of a winter dairy. Everybody tried to set his milk during the summer. May, June and September were the chosen months for packing the surplus butter for winter use. In the East where the dairyman had at his command soft water and cool dairy cellars, the butter that had been packed the year before was a very creditable article. Having packed butter so that it kept nice and fresh there for months, it was natural to suppose I could do the same when my dairy work was taken up in Colorado. But it proved to be an altogether different matter. Although I had the best of dairy appliances—Cooley creamers, ice, pure salt, and plenty of well-water—used the greatest care in intelligently feeding the cows and making and packing the butter, it failed to keep satisfactorily. Why, I cannot tell unless the fault may be laid to the alkali in the water, and the differences in cellars, the Westerner's cellar being generally inferior to those under the large old farm-houses of Massachusetts. A dairyman in the mountains seemed to have hit upon a solution of the difficulty. His deep cans were set in a running stream of soft water, and a grotto near-by, supplied him with ice and snow. Into square tin boxes were placed bricks of No. 1 butter, each brick wrapped in dairy cloth. The box was then filled with brine and sealed.

When it was opened in the winter the butter was very fine; but every minute after the air struck it, it deteriorated and a small family could not use a 10-pound box of it before it was really rancid. Since the public—that portion of it that do not want to eat oleomargarine—demand butter with the fresh, sweet taste natural to it, it matters little if we cannot suit ourselves in packing it. The dairy utensils of the present day make butter-making in the winter no more laborious than in the summer. If I must be out of milk in any part of the season, I should choose to be without it in May and June; for in those months everybody who owns a cow sends a pat of butter to market, often of poor quality, which breaks the market and makes it impossible to get a living price for even the best. The establishment of creameries promised for a while to overcome that difficulty; but with us, when a constant supply of good butter had held the market steady, and as the summer advanced, prices began to advance also, the farmers became dissatisfied with the price paid them for cream, and took the matter into their own hands, and made all the butter they could, and as they lacked the best conveniences, of course, it was of poor quality, and the consequence was a broken market again. One who intends to make butter at a profit, must have his own especial customers, and supply them with gilt-edged butter the year round, at gilt-edged prices.

The Western farmer works early and late during seed-time and harvest; yet the comparative leisure of his winter months might be turned to golden account if he would provide for a winter dairy. When the farm was once fenced, his corn and wheat fields would yield him a second profit as a pasture, and how easy it would be to supply the best of feed to the milch cows from those enormous Alfalfa stacks. But instead of this, it is not uncommon to see farmers selling their hay and buying their butter, and even going without milk because no one chances to bring it to their doors. Sometimes one will make a start and look up the dairy business with a view to entering it; but the first stump is run against when he finds that an ice-house is a necessity.

I have built a good ice-house with a capacity of 200 tons at a cost of $400. The sawdust had to be brought from the mountains and cost $40 per car-load. The ice-house is double-walled and battened and each wall is faced with tarred paper, the space between being left empty. To delay opening the ice-house as late as possible, I packed 30 wagon-loads of ice at the north side of the building. First some boards were put down to keep the ice from the ground; then the ice was laid as carefully as in the ice-house; joints were broken and cracks were filled with pounded ice. Over the top was spread sawdust about six inches deep; then the top and sides were thickly covered with straw and over the whole was built a rough shed of boards. When the last cake of ice was taken from there, about the first of June, it had not melted enough to lose the sharpness of its edges. We run no danger of a flood to come up and melt ice so put up, at the bottom, but we do have as warm, searching winds as any part of the United States.

In a country where lumber and sawdust are cheap every farmer should have the comfort of a good supply of ice, and that, too, at small cost. Before I could get sawdust I covered the ice and kept it, with coal-dust; but the former is more desirable in every way, in cleanliness especially. The nice butter-color furnished dairy-men makes it possible to produce as fine-looking butter when hay is fed, as when the milk comes from cows that run in a clover field: and when the cream is raised under ice-water, or poured out of a separator, the dairy-man can be sure of gathering what the milk should yield, let the weather be hot or cold.

S. E. H.

Greeley, Colo.

GIVE THE BOYS A CHANCE.—We often see farmers of 60 years who have raised families of from two to four boys, working the farm themselves. The boys have left, gone to the city, and are clerking or trying to build up some mercantile business for themselves. Why is this? Something is wrong somewhere. Did you try to keep your boys farmers by encouragement, or did you discourage them by hard work and drudgery? I fear the latter is too often the cause of the trouble. We can't expect success in any business in which interest is lacking. "As the twig is bent so the tree is inclined." In the boy we have the "twig;" let us try to so shape it that when it becomes a "tree" or man, he will be a model to his fellow beings, a pleasure to his family and an honor to his Maker. Encouragement is what is needed to get one interested. Discouragement while young generally means discouragement all through life. Farmers who work their boys hard for the sake of saving in hired help; who give them no interest in anything about the place; who keep them from school nine months in the 12, are doing nothing to make much more than slaves out of them all their lives. On the other hand, farmers who give their boys a good education and a piece of land for their own use, a pair of steers, a breeding sow, chickens or something of that sort, or who pay their boys for what work they do, are the men who are interesting them. We might go further and help them about their work; show them different hints; get them ideas; talk with them more, get them to read over the agricultural papers and discuss the different subjects; get them interested in the market reports; give them their liberty as much as possible; but impress upon them the necessity of finishing their work first. Encourage sports of all kinds and join them in the same; let them see that you are interested in them, and they will become interested in you and your work. If we were more thoughtful in these matters, I think we would see more boys staying on the farm, and caring for father who has done all he could for them. I will admit that some of our best business men, doctors, lawyers, and clergymen were once farmers' sons, but our cities to-day are more than full, and the chances for young men there are not what they used to be. We can find many a man in the city to-day who wishes he had never left the farm, and many of them probably would never have done so if they had been given a chance and encouraged.

Everywhere.

RURAL SPECIAL REPORTS.

Illinois.

PLEASANT VALLEY, Jo Daviess County, July 22. The weather for the last month has, as a rule, been very hot and showery. As a consequence wheat and oats are rusted badly; but oats and winter wheat are more than average crops. No thrashing has been done yet, but the yield will be good. Hardly a field of rye is to be seen. Spring wheat is little sown and hardly worth cutting. Haying is slow work, but old hay as well as new is plenty and we don't worry about it. Potatoes promise to be abundant and by the Fourth of July nearly every one had new potatoes which were ripe enough to be dry and good. Corn is hurrying along to catch up what it lost in growth in the fore part of the season, and it bids fair to make the loss good. We have had no floods but plenty of rain.

W. S.

Iowa.

DES MOINES, Polk County, July 27.—By the latter part of July we are enabled to tell very nearly what our harvest will be. July has been favorable to the growth of all crops, and they seem to have made up to a large degree what they lost in growth by the wet, cool weather of May and June. Corn will be a good average crop, but will not come up to the crop of last year. Some fields were badly damaged by weeds and grass, and cannot recover. The crop is not so well advanced as it was at this time last year. Our oat crop was very promising, but on July 19 we had a fearful rain and wind storm which lodged it badly, making it impossible to harvest many fields except with a mowing machine. The crop is badly damaged. Hay is about an average; but we have had very unfavorable weather for putting it up, as there has been much wet weather. Oats and hay have been nearly all harvested. Early potatoes are a rather poor crop. They are in better demand than usual at this season and bring 35 to 40 cents per bushel. The acreage under the late potato crop is less than usual, and the crop is generally in poor condition. It got too badly in the weeds and grass during our wet weather. I do not think we will have so many potatoes to throw away next spring as we had last. Vegetables are in abundance and the demand is unusually good. Early cabbages and tomatoes are the only vegetables that are scarce. We will have a good crop of late tomatoes and also of late cabbages. Sweet potatoes promise well. The blackberry harvest is light but the berries are of fine quality. Sweet corn crop is extra good.

F. S. W.

Nebraska.

WESTON, Saunders County, July 20.—

Crops of all kinds are good. We had just rain enough in May to sprout corn. We had lots of rain in June and we had three heavy rains in the fore part of July and the weather continues wet. Harvest is about over, and the grain is growing in the shocks. Wednesday, 17, was the hottest day of the year, the thermometer stood at 102 in the shade. The Rural Potato No.2 was cut in pieces and planted. One hill was destroyed; the rest are doing well. The tops are dark green and very heavy lapping over the ground. The blossom was purple in color. P. P. N.

New York.

MEDINA, Orleans County, July 18.—Good crops of hay and wheat are now being harvested. Barley and oats are looking well. Corn and beans acreage small and looking bad, and on account of continuous wet weather they are very weedy. Our apple crop will be light, and what we shall have will be mostly early varieties. Of peaches and grapes, we have a few—perhaps a quarter of a crop. It has been very wet all the spring, but so far in July, we have had fairly good harvest weather. M.

Tennessee.

NORTHVILLE, Cumberland County, July 20.—We have had one of the wettest seasons known for years. Corn looks well; ears are just forming, but the weather is too wet for vines. Grapes are rotting badly. Farmers are having a bad time to cure their hay. Potatoes are splendid. There are no bugs and the 17-year locusts have all been killed by so much rain and hail—the first time I ever knew hail to be a "blessing." Fruits of all kinds are plentiful. H. H. C.

Virginia.

BOHANNON, Matthews County, July 16—We have been troubled here much less than usual by the Colorado Beetle, but the wire-worm has gone to work in pretty good earnest; he has not confined his work, however, to potato tops, but has been paying his respects to melon and squash vines as well. I. I. P.

Wisconsin.

BRILLION, Calumet County, July 18.—Taken all in all, the season in Eastern Wisconsin has not been so favorable for farmers in many years. A larger area of winter grain than usual was sown in this section. The crop has just been cut and the yield promises to be very large. Oats are very heavy; spring wheat good; barley ditto; hay an enormous crop. The corn crop is backward, and unless frost holds off until late in the fall, it will not amount to much, still this is not a very important factor in the harvest, in this immediate vicinity. Prices of milk, butter and cheese remain low; yet the abundant pastures and heavy yield of milk in part compensate for the low prices. Prices of cattle are low. This seems in part to be owing to the large receipts at the centers of trade and in part to a combination of packers to keep prices down. Armour & Co., of Chicago are destroying our local markets here in Wisconsin. Formerly our flourishing manufacturing cities furnished a market for a large quantity of meat at about Chicago prices. Now in every city of any considerable size this company has a distributing depot for its dressed meats, and compels local butchers to purchase of it, threatening, in case of refusal, to open retail houses and destroy their trade, by underselling them. In Wausau an indignation meeting was held among the business men, and citizens generally to protest against this action on the part of the above firm. It is claimed that farmers must send good stock to Chicago, at ruinously low prices; while poor beef is sent back to them and butchers must pay the monopolists their price. There is a screw loose somewhere, since every man that buys a piece of meat must pay a tax to add to Armour's millions. E. G. F.

OATS FOR THE SILO.

T. J. H. Wheeling, W. Va.—Have any of the RURAL readers had experience with oats for the silo? At what stage of its maturity should it be siloed. What would be the quality of the silage?

FROM DAIRY COMMISSIONER, J. K. BROWN.

I have used nothing as yet for the silo, except corn. I have found it to be of very great value as a soiling crop.

FROM SMITHS, POWELL & LAMB.

We have used green oats for ensilage with good satisfaction. The yield was very large per acre. We cut it a little too green—just as it was coming into the milk, not fully headed—and put it into the pit very green and damp. Cattle ate it well and cows fed on it milked well. Had we dried it a little—just enough to prevent any escape of sap—we are confident the result would have been most satisfactory. Clover for ensilage is probably second only to corn. We have tried rye, but think little of it. Wheat is good. We have had good results with Timothy and nearly all other grasses. Our experience favors, first, corn; second, clover; third, oats, etc.

FROM H. S. WEEKS.

I have never used any crop in the silo except corn, for the reason that, all things considered, it is the cheapest; but I believe that if cows are kept up the year round, (and I am looking toward that system) there are other crops which can be grown expressly for silage to advantage; for while corn silage has been fed to milch cows continuously for 18 months without apparently doing them any harm, and with profit in their performance at the pail, yet on the ground that a more perfect ration can be secured cheaper than by balancing corn silage wholly with grain, by filling the silo partially with some other forage crop, notably clover, I propose to put it in practice another year. In the absence of clover, which is not a sure crop every year in this latitude, peas and oats, it seems to me, should make an excellent substitute, and I am prepared to experiment in that direction in a moderate way this season, having a few acres of oats put in late expressly for the purpose. I also hope to put some Hungarian in the silo provided it is not all needed for soiling, and with the continuance of the frequent showers with which we have been blessed this abundant year, pastures bid fair to hold out till corn fodder is far enough advanced to bridge over any shortage which may occur later. After three successive years of protracted and severe drought, we have all learned to be well fortified with soiling crops to arrest the terrible running down of our cows in milk at this season. When, I say "all," I mean all who are farming for *profit*.

PREPARING A FIELD FOR HAY.

J. I. L., Tranquility, N. J.—I have a field I wish to use exclusively for hay. I sowed Timothy and clover in oats, but was much disappointed when I mowed the field last year, so I acted on advice and let it lie until this year, with the same results. I am a young farmer. I want to treat this field in the best way. How can it be done?

ANSWERED BY HENRY STEWART.

The very meager statement given precludes any specific advice in this matter, for not knowing the condition of the field, it is quite impossible even to suggest any cause for the failure except the poverty of the soil. Grass and clover, contrary to the prevalent belief, or rather, practice—for farmers frequently seed down land to grass and clover in spite of their knowledge that the land is not in fit condition to produce a crop of anything else—require as good soil for successful growth as corn or grain. No doubt the disappointing result in this case is due to want of the requisite fertility of the soil, which grass and clover need. Had the land been manured or fertilized, no doubt the result would have been different. The description of the methods practiced by farmers who make a special crop of grass for hay, recently given in the RURAL, fitly applies to this and all other similar cases. Grass, either with or without clover, is the most valuable and profitable of all farm crops, and it is indispensable that the land for it should be prepared in the very best manner. In many years' practice I have never failed to get a good catch of grass and clover, or either alone, with whatever other crop it was sown, or when sown alone, when the land was well prepared by good culture and was liberally manured or fertilized; and I have never had a satisfactory result when seeding land under any other circumstances.

It might be suggested that this land should be plowed and resown, for a poor grass crop is like a poor cow, wholly unprofitable and wasteful of labor, time and money. But the ground should be well turned and harrowed thoroughly; if there is no manure at hand 500 or 600 pounds of the complete artificial manure should be applied; more would be better, up to 1,000 pounds to the acre. Rye may then be sown and one peck of Timothy seed per acre sown as soon as the rye is harrowed in. The land may be leveled over the grass seed with a smoothing drag, a heavy plank drawn so as to pass diagonally over the harrow marks, for grass seed needs covering quite as much as rye does. Early in the spring when the land is loosened by a light frost, one peck of clover seed should be sown to the acre. I prefer the Perennial, or Crimson Clover, commonly called Pea-vine Clover for several reasons: it makes a heavier growth; is fit for cutting with the Timothy, (my clover of this kind with Timothy, is now, July 25, just half in bloom with the other half just ready to bloom) and it lasts several years, making, the second and third years, the very best of hay and the heaviest yield I have ever secured. The thick seeding is necessary to avoid the too heavy and sappy growth of vine. Then I have no doubt the result will be fully satisfactory.

SHOE-BALLS ON ELBOW OF A HORSE.

L. D. C., Detroit, Mich.—My horse has a shoe-gall—a lump on the fore-leg just below where the leg joins the body—caused by injury from the calks when the animal lies down. About three weeks ago it broke. A veterinary surgeon on three visits prescribed bathing the sore for 15 minutes, nights and mornings, with warm water, and then injecting something to cause inflammation. The sore, however, is no better than it was three weeks ago. How should it be treated?

ANSWERED BY DR. F. L. KILBORNE.

If you have employed a competent veterinary surgeon we would advise you to follow his directions carefully. These "shoe-balls" or "shoe-galls" are often very obstinate and difficult to remove when large or of long standing, and several weeks or even months may be required to effect a cure. In the meantime the foot that caused the injury must be kept well padded at night or the horse must be kept standing to prevent further irritation to the elbow. Without this precaution, treatment will be of little or no use. The following is a general line of treatment which may be varied to suit special cases: when the tumor is recent and unbroken, bathe frequently with hot water until the heat and tenderness have subsided, then blister or apply compound tincture of iodine daily until the swelling is absorbed. When discharging, the cavity should be thoroughly washed out once or twice daily with some astringent, or antiseptic wash, as carbolic acid one ounce in a quart of water, chloride of zinc one-fourth to one-half an ounce in a quart of water, lead acetate and sulphite of zinc each one-half ounce in a quart of water, or other similar wash. The outside should be painted daily with the iodine as above. An iodine wash or ointment for the open sore, if unhealthy, may sometimes be alternated with the above washes to advantage. Finally when reduced to a moderate size containing a hard lump or tumor, it may be carefully dissected out and the cavity be allowed to heal as an ordinary wound.

CAULIFLOWER CULTURE.

S. S., Benton Harbor, Mich.—1. How is cauliflower raised? 2. Would well-drained muck pasture land, as yet unplowed, be desirable? If so, when should it be plowed and how prepared for next year's crop? 3. Which are the more profitable—the early or late varieties? 4. What mistakes would a beginner be likely to make that would cause failure or mar success?

ANS.—1. The seeds are sown, the plants transplanted, and the after cultivation given the same as for cabbage, except that the distance between the rows must be greater, not less than three feet, and more for the large varieties. 2. Yes; but it would have been better, had it been well manured, and planted with corn, or some other hoed crop this year, but it may be plowed in the spring, being careful to have the sod well inverted, and then thoroughly and frequently worked until it is time to set the plants. Stable manure should not be applied the same year the crop is grown, unless for an early crop, but commercial fertilizers, strong in potash, or ground bone are beneficial. The cauliflower growers on Long Island use fish guano with excellent results. 3. Market gardeners in this vicinity say the very early, or the late crops pay best, but this depends on the demands of the market. We should not plant very extensively for an early crop, as the demand is limited, and the crop cannot be held. 4. Some of the mistakes that occur to us are sowing cheap seed, that is, seed which is low in price; going into the business on too large a scale before any experience has been acquired, and not giving thorough cultivation. Frances Brill, Riverhead, Long Island, and J. J. H. Gregory, Marblehead, Mass., each publish a small pamphlet on cauliflower culture, which we would advise our friend to get and study thoroughly before beginning operations.

PERIODIC OPTHALMIA; WORMS IN A COLT.

H. B., Belle Plaine, Iowa.—A mare of mine is troubled with a bad eye. First the sight appeared weak, and water would run from the eye. Gradually the pupil became cloudy until the animal was almost blind, and the eye looked as if it were a glass ball filled with milky water. In time this became quite clear, and the animal could see again. This has happened several times. She has a suckling colt which is troubled with worms; what should be the treatment?

ANS.—For the mare see treatment for periodic opthalmia, frequently given in these columns. She will probably eventually become blind. Colts may have several kinds of worms and in different parts of the system, on the lungs, intestines, etc., each of which requires special treatment. You will have to be more definite. Locate and describe the worms if you have seen them; if not, how do you know the colt has worms? We can then advise treatment.

GRASSES FOR A LAWN.

F. H., Paterson, N. J.—What kind of grass seed would be best to make a good clean lawn?

ANS.—Blue Grass and Red-top or either separately. For the Middle and Northern States these are the basis of all the high-priced lawn mixtures. They are as good as any.

Miscellaneous.

W. E. B., Richmond, Ind.—Where can I procure Actinidia polygama, lately described in the RURAL?

ANS.—From Ellwanger & Barry, Rochester, N. Y.

E. C. D., Waunakee, Wis.—Where and at what price can I purchase a dozen Parker Earle Strawberries?

ANS.—Write to T. V. Munson, Denison, Texas. We do not know the price.

M. W. H., Carlisle, Ky.—Grub-worms are destroying my strawberries; is there any remedy for them?

ANS.—We do not know of any remedy except winter plowing or spading or a change of plot. They are usually worse on a freshly turned under grass sod. These grubs are the larvæ of the May-beetle.

C. T. S., Swanton, Md.—Where strawberries are kept in hills and fruited only one year, what are the objections to seeding to clover in the spring before fruiting? Would the young clover keep the berries clean!

ANS.—The clover would shade the plants too much besides drawing heavily upon the moisture and nutriment of the soil.

Elva, Bucks County, Va.—How should snap beans, tomatoes, etc., be prepared for evaporating.

ANS.—The R. N.-Y. knows of no method by which snap beans and tomatoes may be successfully evaporated on a small scale. The large evaporators have special machinery for preparing fruits and vegetables rapidly and economically. We should like to hear from any of our readers who have had experience in this direction.

A. S., Jacksonville, Fla.—Is "mullein tea" good for relieving hide-bound horses? If so, how should it be prepared and where can it be obtained?

ANS.—We are not aware that mullein tea possesses any special value as a remedy for hide-bound horses. If you had given the age of the horse, general condition, feed and surroundings, and probable cause of being hide-bound, if known, we might have advised suitable powders to relieve the condition.

E. T. R., New York City.—Would a Hackney stallion on Thoroughbred mares make good hunters and coachers? Who in England breeds Hackneys and what do they cost?

ANS.—This cross would probably make excellent hunters for light weights. For heavy weights, however, less of the Thoroughbred blood would be better. For first-class coachers a cross of a stallion of the French Coacher or Cleveland Bay breed would doubtless prove more satisfactory on a half-bred thoroughbred. John J. Lewis, Cardiff, England; Samuel Rose, Huntington, England; and Alexander Morton, Gowanbank Marvel, Kilmarnock, Scotland, advertise Hackneys in the English papers.

Miscellaneous Advertising.

"Herbrand" Fifth Wheel for Buggies.

DISCUSSION.

THE IDLE POOR OF THE CITIES.

C. W. W., HURON COUNTY, OHIO.—On page 448 the RURAL asks: "What is to be done with the idle poor of the cities?" Judging partly from history, partly from observation, and partly from self-consciousness, I believe that idleness is not congenial to the American people, or to the Northern European races that have come among us. Like the use of opium, tobacco and alcohol, however, indulgence in it doubtless begets a tolerance for it, which ultimately may become a craving. Possibly, too, this unnatural vice may even in some degree become hereditary.

I would ask these questions: Are there places where all those who are idle might find work? Are any of the productive industries of the country seeking the services of these idlers, or is it not, rather, true that every one who finds a place where he may earn his living thereby displaces some one else? I saw an extract not long ago from a business journal in the iron trade, in which was shown the great economy effected by the substitution of crude oil for coal in the production of steam. This change, which was effected between October and March last, had in the Chicago Rolling Mills alone resulted in the displacement of nearly 100 men, while it had rather increased than diminished the out-put of the concern. An equal displacement must have occurred in the coal-mining, carrying and handling industries in consequence of this same improvement. Is it not true that the economies which are being so rapidly made in all lines of industry are of the same kind—always increasing the producing power, while employing a smaller force of laborers? If so, what wonder that "this worthless, idle class is constantly increasing in numbers." As each economy is effected, a new adjustment takes place. The workers jostle each other on, and, with some exceptions which are not hard to find, those who are finally displaced from all employment will be those in whom the tenacity of the working habit has become most weakened. But, if this is true, the existence of this class of idle poor is but a symptom and not a disease. The work of the world is now done through costly machinery, by methods which are very efficient. This puts great wealth within the reach of a few, but, unfortunately, it is not evenly enough distributed. A very unfairly large proportion of it rewards capital; while too little of it pays labor. Among the people there is need enough of the products of industry, but there is a lack of purchasing power where the need exists. There is power enough to supply all that need work, and more, but that power can not be applied to production for lack of a market. Even as it is, more energy is expended in selling most articles of consumption than in their production, and their price is more than doubled to the consumer by that fact. Should those who have been crowded out, go to work simply on their own energy? In order that they may buy anything they must sell a part of the product of their own industry. But in order to enter the market, they must produce an article as good in quality and as low in price as that which already holds it; hence they must work in the most efficient manner, through the machinery by which the line of goods which they would put in the market is produced. Unless they are to produce everything for themselves, shelter, food and clothing, and have nothing to sell, they must become employés. If, failing to find employment, they should try as best they could to supply their own needs, a Digger Indian would be better off than they; but even in that case, there is no place where they might stay and illustrate their independence. The problem to be solved, then, takes such a shape as this:

1. To provide an opportunity for every person to apply his unit of energy in the most effectual known manner, in supplying the needs of the world.

2. To identify the commercial demand with the needs of the people.

These two are the complements of each other. One cannot be solved without the other, but these requirements being satisfied, poverty would thereby be abolished. Given the power, is the world willing to abolish poverty? I have never known an instance where a sufferer from poverty would not be glad to abolish his own, but when it comes to abolishing poverty generally, I fear there will be great resistance.

WHY FARMING "DON'T PAY."

E. L. F., ELBA, N. Y.—I see of late a great deal about "farming don't pay," in every agricultural paper. Why does not farming pay? Is it on account of over-production or owing to the slack and slovenly way in which the business is carried on? A great many suppose that any one can farm. That is where many make a mistake: all of us who have been brought up on the farm are not farmers. As I was riding through a neighboring town last spring, I saw a field on which manure was being drawn. The heaps were mostly coarse straw and there were about two bushels in a heap and 30 feet apart. I stopped and asked the man what crop he intended to put in there. He said: "Oats." I asked him if the land was rich. He said no it was very poor. He thought if he gave it a good coat of manure he would get a good crop. This man is one that says; "Farming don't pay," and I should say he need not go to a guessing school on that point. Then there are other men who will plant a little patch of corn, a little one of potatoes, a little one of beans, a few acres of wheat; the same of oats, a little of everything, and when harvest comes, they have a little of everything and not much of anything to sell with which to pay their debts. Instead of raising a crop of some one thing, and having a crop to sell, such men fritter away their time and labor and say they don't think farming pays now.

I am acquainted with another man who has a large farm, but who is a good deal in debt. He grumbles all the time about hard times; but his binder is out in the orchard housed under an apple tree; his harrow is in the fence corner in the field, and his wagon is outside the barn. Next spring when he wishes to use these tools, he will find them ready for repair, and he will say nobody can make farming pay in this country.

Another man that I know of has 100 acres and last season he raised on his farm 1,100 bushels of wheat; 800 bushels of barley; 500 bushels of oats; 1,100 bushels of corn in the ear; 80 bushels of potatoes; seventy-six tons of hay; besides apples, pears, peaches, strawberries and raspberries. He feeds out all his corn and a good many oats; fattens ten or twelve steers every winter, and makes about 400 loads of manure every year. He makes farming pay.

W. F., GLEN COVE, N. Y.—Apropos of Rambler's "Long Island Notes," page 475, I would say that hereabout the truck business is passing out of the hands of the old American families because the young folks in these families take to "nicer" employment. Potato beetles were never before so abundant as they have been with us this year. Instead of giving two doses of Paris-green, as we used to give our crop in years past, I have poisoned our potato vines four times this year, and tomatoes, egg-plants and tobacco have only been preserved alive by poison and hand-picking. Last year's prices for asparagus ruled very high the whole season through; this year to begin with, prices ruled very low, but in a couple of weeks they advanced to living rates. Out of 29 kinds of strawberries I had this year, Sharpless was the best of all in weight of crop and the fine appearance of the berries. This variety seems particularly adapted for our heavy land, but it is useless on the light soil. Again, some of my neighbors say that Sharpless is unsatisfactory with them. So with strawberries in particular, it is a matter of certain kinds for certain soils and locations; but, taking it all through, I think Sharpless has a wider range than any other large-fruited variety.

"A SIGNIFICANT MOVEMENT."

V. H. F., ALBANY, N. Y.—The recent meeting at Rochester of the representatives of organized agriculture in this State, noticed in the last RURAL, is certainly a move in the right direction. The farmers of New York, in common with those of other States, have suffered from the oppression of organized capital, brought to bear upon the law-making and law-executing powers, if not upon the judiciary as well. If any one doubts this, let him study the history of attempted agricultural legislation in the different States the past winter. How many dressed-beef bills, oleomargarine bills, and other acts clearly in the interest of farmers, were ignominiously defeated? Of a long list of laws passed in New York at the last session by a Republican Legislature, and signed by a Democratic Governor, not a single one was of any special importance to farmers, the most numerous class in the State. Money was voted with a lavish hand to placate other classes, *e. g.*, the law providing that the laborers on all State works should receive not less than $2 per day of eight hours. This was a bid, pure and simple, for the labor vote, but here, with a stupidity that illustrates their unfitness for the positions they hold, these demagogues neglected to make appropriations for these increased expenditures, so that their work is likely to recoil on their own heads. By the provisions of this bill, laborers on the Erie Canal who never pretended to really earn the $1.50 formerly received for 10 hours' work, now receive $2 for eight hours. Lock-tenders who used to fight bitterly for a position paying $40 to $45 per month, now receive $60 per month, as they must work 12 hours each day. Was this legislation called for? Most emphatically not, and no one who favored it should ever receive a farmer's vote for any office again. But how does this affect the farmer? It adds to his already too heavy taxes. Its tendency is to increase the price he must pay for labor. No man will work on a farm for the wages a farmer can afford to pay, when he can get a "soft" job for 25 cents per hour. It tends to make farm help dissatisfied and exacting, even though but a small percentage of the laboring class can find employment on public works. This is but one example of many that might be given to show the need of farmers' organizations. Farmers have been too much the slaves of party. Other classes have learned the folly of this, and have proved the power of organization. Farmers in some parts of the country have done the same, but when the farmers of the whole country unite in common cause, their power will astonish the world.

THE DAVIS SWING CHURN.

E. H. ANDREWS, GLASTONBURY CREAMERY, CONN.—Let me add to the discussion on churns by answering the following questions.

"Can you get more butter by using the Davis Swing Churn than by using another?"

I say, yes.—We do get more butter from the same amount of cream, because it thoroughly churns all the cream, completely separating the butter from the butter-milk. A careful farmer living near our creamery, who has used one of the most noted cylinder or crank churns, finds that so much cream sticks to the arms and the inside of his churn, before the butter comes, and is afterwards washed off into the butter-milk, that in churning that over, he has sometimes made from his butter-milk a pound of butter for each six to eight pounds of butter made directly from the cream. One of our patrons recently received a letter from a dairyman in New Jersey, saying that he had made a discovery worth patenting—that churned butter-milk would yield from one-fifth to one-eighth as much butter as cream. The Davis Swing churn has been tested here with several other kinds, and never came out second best, and its butter-milk has no cream left in it and will not make butter.

"Is the butter made in the Davis Churn of better quality than that made in other churns?" To this I answer without hesitation, yes. The butter comes in grains about the size of wheat, varying slightly in size with the temperature of the cream. These grains of butter are easily separated from the butter-milk, almost every drop of which can be washed out; while the unbroken grains of butter remain in the churn, and can be placed on the butter-worker to be salted and balled, without giving the butter any of the "salvy" look, which comes from mashed and broken grains, so common from other churns. Butter so made, not only looks better, but tastes and keeps better.

"Does the butter come in a shorter time?" No, I do not think it does. Some rotating and beating churns bring butter a little more quickly; but the Davis Churn will bring it as quickly as any churn can do it, and do it well. We vary from 30 to 40 minutes in churning from 80 to 100 pounds of butter.

"Is running the Davis easier work?" I think it is. The smaller sizes can be pushed back and forth as easily as a cradle, and with our larger-sized churn the power required to swing it is very little.

"A TARIFF ON BANANAS."

F. R. W., MONROEVILLE, N. J.—I was much interested in an article on a "Tariff on Bananas," in the RURAL of July 20th, as an import duty on them would influence the price of other small fruits, especially strawberries. I grow strawberries myself and suffered this year from the low prices. In order to ascertain the cause and to see what I could do to improve the sale of my own berries, I went to Philadelphia in the hight of the season, stayed all night with my brother who is a commission merchant, and was in the market by three o'clock a. m., and was completely surprised—almost dumb-founded—to see the quality of the bulk of the fruit that was put on the market. Loads after loads of strawberries were piled up in front of Dock Street Market that morning, that were not worth picking, much less paying freight and commission on. They sold at from three cents a quart to 50 cents a 60-quart crate, and brought all they were worth. I was satisfied that the reason why we have to take such small prices for our strawberries, is on account of this worthless stuff flooding the market. If something could be done to stop this trash from coming into the market, we could get a better price for our fruit. It does not seem to me that putting an import duty on bananas would do any good; for when a man wants a banana he certainly would not buy a box of strawberries. I think one mistake a good many growers make is in letting the plants make too many sets. If we would shorten the runners in rows we would have fruit of a better quality, though less in quantity, and quality is what we want.

What Others Say.

MR. CRAWFORD'S STRAWBERRY REPORT FOR 1889.

OMITTING THOSE OF WHICH A SPECIAL REPORT IS MADE ON PAGE 522.

THE safest way for those who want better strawberries than those they now have is to test the new kinds for themselves. This costs far less than is generally supposed, and is the only way of judging correctly. An outlay of about two dollars a year would enable a person to do the work. He need not occupy over half a rod of ground with a single variety, and he should always test the best that he already has alongside the new candidates. A single season's experience is not always conclusive, for a variety may do well one year and make almost a failure another, but the following notes will show what most of the new kinds and some of the old ones did for Mr. Crawford this year. His farm is at Cuyahoga Falls, O.

CRAWFORD.—The plant is very large and stalky, dark green, and free from defects. It has a perfect blossom, and is a good bearer. The fruit is large to very large, somewhat irregular at first, but never coxcombed. Color, bright, glossy red, and lighter within. The flesh is firm, and of excellent quality, one of the best. It produces a good number of strong runners, and is a variety of decided character.

DAISY. Mr. Crawford finds to be vigorous, productive, early, large, roundish, bright red, and of good quality.

MIAMI.—This is a good grower and bearer, very late, and of good quality. He has fruited it in a small way, and believes it to be valuable.

OSCEOLA.—This is claimed to have many good qualities, and to be the earliest of all.

WARFIELD.—Whosoever has this may congratulate himself, for it is a very valuable sort, and more likely than any other to supersede the Crescent. With us it is equal to that variety in health, growth, and productiveness, while it is far superior in size, beauty, and firmness. It is wonderfully productive, and continues of good size for a long time. It has a tart, agreeable flavor.

CLOUD.—Mr. C. expected this to be very early and immensely prolific, but was disappointed. It commenced to ripen about a week later than the early sorts and was only moderately productive. It produced the most on the poorest soil. When grown in the matted row on very rich ground the leaves were about two feet high, but there was very little fruit.

PINEAPPLE.—This was a disappointment to Mr. Crawford, as it proved to be neither more nor less than the *Bonanza*, a variety that he tested and discarded some years ago. It was originated and named at Ada, O. A. M. Purdy, who had it on trial, renamed it *Pineapple*. It came to the surface again in Maryland last year, as something new, and was so well recommended that Mr. C. procured a stock. This last spring he sent for more, and planted half an acre, all of which he will destroy. The fruit is large but terribly misshapen, salmon-colored throughout, and as salvy as a banana.

HAMPDEN.—This was unsatisfactory in growth, and many of the berries failed to reach maturity. The fruit is quite sour and lacks gloss.

LOUISE.—Mr. Crawford had only a small bed in bearing, but he is inclined to think well of it. It is only a moderately good grower, but bears abundantly, and the fruit is of good size and quality. Some of the largest specimens are slightly misshapen, but usually they are of good form and fine-looking.

GOLD.—This is less productive than expected, but the fruit is good and very uniform in shape. It is round and rather light red. The plant is strong and healthy.

BOMBA.—This is all that was claimed for it. The plant is vigorous, sends out a moderate number of runners and makes a great many crowns. It produced a large amount of fruit that ripened early, and was of great size, dark color, firm flesh, and quite satisfactory

quality, and as uniform in shape as the Cumberland. It is esteemed for canning.

BURT.—This is the old Capt. Jack under a new name.

GANDY.—This is late, and bears a fair crop of large berries toward the close of the season. The plant is large, strong and healthy, and a good grower.

SUMMIT.—This did well, as usual, and furnished fine berries late in the season. It is quite a favorite with Mr. C., but is not generally popular on account of its inclination to rust.

MONMOUTH.—This ripens with the early varieties, and produces a fair amount of fruit that resembles the Wilson in size and shape, but it is not nearly as productive as the Warfield or Haverland.

The MAMMOTH grown in matted rows is such a poor bearer that it yields no profit.

CUMBERLAND and MAY KING did well this season as usual. They are both too well known to need description.

OHIO.—This was Mr. Crawford's latest berry this year, and he would esteem it above any other late variety if it were only larger. It is so productive, stands up so well, and is of such a brilliant scarlet color that it is quite satisfactory both to producers and consumers, although no larger than the Crescent.

HENDERSON.—Mr. C. is obliged to give this up, although it is not surpassed for quality. It is unproductive and ripens unevenly.

FALL PLANTING.—By this is meant the transplanting of runners of the present year's growth, whether it be done in July or October. By care and skill it may be done as soon as the young roots are an inch in length, or even earlier. The rule is, however, that a plant is not old enough to set until it has branched roots; nor is it self-supporting until some time later. For this reason it is necessary to remove one or more of the leaves when setting out very young plants in the summer, lest more sap be evaporated than the roots can supply. As the season advances, more roots are developed, and there is less risk in the operation. While it is true that the earlier the work is done, other things being equal, the greater will be the crop, it is equally true that plants set early in September, when there is more moisture in the air and soil, usually do better than those set in a hot and dry time. It delayed too late, the danger is that they will not get sufficiently rooted to enable them to resist the effects of alternate freezing and thawing. Young plants in the summer are comparatively tender and sappy, and much more easily injured than when more mature. If taken out of hard ground, the roots may be bruised or broken, and if exposed to the sun or wind for even a few minutes, many of the fine hair roots will be destroyed. For this reason it is not best to take up plants in a dry time. It is better to let them grow where they are until rain moistens the soil so that all the roots may be lifted without injury. The later the work is done the closer should plants be set to each other, so that they may fill the row with roots and shade the surface with their leaves. If set 12 inches apart in the row in July, 10 inches will be enough in August, eight in September and six in October. The sun should never be allowed to shine on bare ground between plants in the row during the winter or early spring.

The soil for fall-set plants should be rich, so that their roots may find what they need near-by, for they have not time to go far after it. It is well to prepare the place a week or two in advance, so as to let the ground get settled. And it is very important that the crown of the plant be not covered.

If the weather be dry and hot after planting, so that the plants wilt, they should get *one* good watering in the evening and the soil should be stirred the next morning. If this prove insufficient, they should either have some shade during the heat of the day, or the first leaves that wilt should be removed to lessen the evaporating surface.

If it is desired to test a new variety, the fall is the best time to plant it, for the reason that it will bear the next season and enable one to decide as to its value and give ample time to greatly increase the stock.

Fall-set plants must be protected during the winter. Two inches of straw will answer. Of course the drainage should be such that no water can lie on or near the surface.

When plants are received in a dry time, it is an excellent plan to plant them temporarily two or three inches apart in mellow soil where they can be shaded and watered. In a few days new roots will be formed, when, after a thorough watering, they may be removed with the soil adhering and set without a check.

SUMMER PRUNING.—The shearing of a tree or shrub into some formal shape, as of a cone or hemisphere, may have a proper place in some styles of gardening; but, in general, it may be said that the clipping of trees or shrubs into any set form is radically wrong. The experienced Jackson Dawson, of the Arnold Arboretum, said in Garden and Forest that he had seen many good collections of shrubs ruined because each one was cut into a shape to resemble all the rest. In this way all individuality is lost, whereas the object of pruning should be to develop whatever beauty each plant possesses on the lines of its natural growth. It is utterly impossible to secure any fine effects in large shrubberies where each individual is trimmed after the same pattern. Evidently the true way is to encourage each one to make the best of its natural graces, and then to arrange this infinite variety of form into a harmonious picture.

If we prune for the purpose of increasing the flowers of a shrub or tree, we must prune different species and varieties at different seasons of the year; but surplus wood and suckers can always be thinned out during the summer season, and wounds which are cut clean in midsummer will heal more quickly than those made in frosty weather. Maples, birches, yellow-woods and many other trees bleed copiously when their branches are cut in the spring, but they heal over more quickly if pruned while in full leaf. Again, shrubs which bloom on wood made the previous year, of which the early spiræas, forsythias, honeysuckles, viburnums, syringas, philadelphus and deutzias are examples, should receive their chief pruning soon after the flowers have fallen. This will encourage a growth of young wood with flower-buds for the following year. Of course, when these shrubs are cut back in early spring before flowering, the flower-buds are sacrificed. On the other hand, shrubs like Hydrangea paniculata; Desmodium penduliflorum, Hibiscus Syriacus and others, which flower on the new growth, bloom more abundantly when cut back severely in early spring. But even in this case the surplus wood should be thinned out during the summer.

After the branches of large shrubs have been thinned out, continues Mr. Dawson, stronger shoots should be pinched back with the thumb and finger, for this will hasten the growth of flowering-buds. Many trees and shrubs can be made to produce flowers and fruit at a smaller size than if they were left to themselves or pruned only in the winter or spring. This summer pinching also helps to ripen up the wood, and leaves it in good condition to withstand the cold. He has known trees which were tender, when left to grow naturally, to endure our winters fairly well when the wood had been properly stopped by pinching it in summer. This is especially true in wet seasons, when the branches often continue to grow until the frost kills them. Apples, peaches, plums, filberts and many other trees can be made to bear when quite small if the new growth is stopped once or twice in the summer. Mr. D. has peach trees five or six feet high which are loaded with fruit, the result of pinching back in summer. While trees are growing vigorously the flower-buds do not form well, but by this summer pinching the flow of the sap is checked and the buds are developed. Many plants also ripen their fruit better when the strong shoots above the fruit have been stopped. Young trees can be easily trained with very little use of the knife when they are taken in time, the surplus buds rubbed off from the lateral branches and the branches properly pinched back. In short, summer pruning is useful and indispensable for the removal of superfluous branches in the middle of the tree or shrub, and for the shortening-in of all over-vigorous branches and such as interfere with the native symmetry of the tree; and by thinning out the weak and misplaced branches additional nourishment is supplied to those that remain.

THE LATEST AND BRIEFEST.

DR. HOSKINS says, in the Mirror and Farmer, that our high-grade butter is primarily a table luxury, and is only secondarily to be considered as a food. Up to a recent date, in countries where cows, goats and sheep abound, butter has stood upon about the same basis as lard and tallow, the price being but little more and the quality often not as good.

WE farmers are apt to complain of the increase of wealth in our cities; but dairymen ought to know that without this numerous wealthy class, whose members are eager for every sort of luxury of the table, there could be no sufficient market for the extra qualities of food, which alone offer encouragement to superior knowledge, taste and skill upon the farm. The elevation of the farmer intellectually and socially is closely allied to those social conditions among the well-to-do who must buy their food of those who produce it. The high-class farmer can live and thrive only by the aid of a class of patrons able to pay well for those luxuries of life which such farmers alone are able to offer .....

THE BREEDER'S GAZETTE has been making inquiries as to the efficacy of the newly-invented "chemical dehorners." Nearly all the replies testify to complete success of the liquid horn-killers. A few failures are instanced. One correspondent avers that after a careful application of the chemical to the head of a young calf—directions being followed closely—one horn germ was effectually killed, while the other waxed strong and grew vigorously, just as though the horn-killer were a horn-tonic.....

THE good Thomas Meehan—he has done a power of good in his time—calls attention, in the Weekly Press, to several matters which may well be repeated in our columns: Some persons have a fancy for having Hydrangea paniculata as a standard. To accomplish this object cut away all but one shoot, which tie to a stake. In a season or two the stem will support itself.....

IT is the usual practice Mr. Meehan continues, to sow hollyhock seeds in spring, but if gathered and sowed as soon as ripe, plants will flower the next year, thus saving a whole season.....

TRUMPET Vines (Bignonias) are very pretty when made to become standards. Drive in a four-foot stake, tie the vine to it and let the stake be until it rots away. By that time the vine will hold itself, and it will flower perfectly every July.....

THE native Hydrangea quercifolia, commonly called the Oak-leaved, is well worthy of a place in gardens. Though a native of Georgia and Florida, it is quite at home here. Its large leaves are as broad as long. The immense panicles of flowers, though not of such individual beauty as are those of Paniculata, are most attractive, and then it flowers in July when bloom in the shrubbery is scarce...

FROM present appearance the R. N.-Y. will have a very good word to speak for Hendersons Dwarf Lima (Sieva). It seems at least 10 days earlier than the pole Lima and the little bushes are very prolific. Many will prefer the pole Sieva, as it is about the same in earliness. But there will be a place for the dwarf.....

THE LONDON AGRICULTURAL GAZETTE says that the results previously observed of the Woburn experiments are particularly marked this year, the contrasts between plots differently treated being more than usually striking. There are some very fine pieces of wheat and barley on plots dressed with liberal applications of nitrogenous and mineral manures. On the other hand, the plots to which only minerals have been applied have produced very little grain in comparison—only about as much as is growing on the land left unmanured during 13 years of continuous cropping. The transient effect of nitrate of soda or salts of ammonia is very forcibly illustrated, especially in the case of wheat. *Plots which produced 29 to 30 bushels of wheat last year after being dressed with mineral and nitrogenous manures, look like yielding only 15 to 20 bushels this season, when the same minerals have been applied without the ammonia salts or nitrate of soda. Again, plots from which only 12 to 18⅓ bushels were obtained last year, when minerals were only used for them, promise to give 36 to 50 bushels this season, the nitrogenous manures having been restored to the mixtures applied to them.....*

SUCH figures show, as far as one set of experiments may be employed towards a generalization, that nitrate of soda and sulphate of ammonia only act materially upon the wheat crop for one year, and that as soon as they cease to be applied the land is reduced approximately to the condition of the unmanured plot—and that in spite of the constant addition of mineral salts.....

ALLUDING to a recent visit to Dosoris, the beautiful island home of the editor of the New York Sun, Garden and Forest says that though the rose season was over, the pink, ever-blooming Bourbon Rose, Mrs. Degraw, was loaded with flowers, and it was pronounced by both Mr. Dana and Mr. Falconer the best garden rose in the entire collection...

THIS island contains about 45 acres. Mr. Dana one year bought and spread upon it 5,000 loads of stable manure. His ordinary annual supply is about 1,500 loads brought from New York by schooner.....

For Mental Depression
Use Horsford's Acid Phosphate.
Dr. L. C. S. TURNER, Colfax, Ia, says: "I am very much pleased with it in mental depression from gastric troubles."—*Adv.*

ABSTRACTS.

——HUSBANDMAN: "A wise course for a farmer who thinks work at the experiment farm is scientific tom foolery is to go himself to see the work before he expends much energy in condemnation."

——HOARD'S DAIRYMAN: "The good cow is a wonderful machine—almost a creator; for, feed her $40 worth of appropriate foods, per annum, and she will furnish a family with more food than they can buy in other as palatable forms for $100."

——PUCK: "To-morrow is longer than last year."

——VERMONT WATCHMAN. "An exchange says: It is constantly preached that farmers should 'be educated, should read, should profit by others' experience, etc., yet it is quite generally conceded that the most dismal failure of a farmer is he who 'knows it all.' But the reading farmer reads because he does not 'know it all' The know-it-alls have no occasion to seek information."

——BOSTON GLOBE: "It is undeniably a fact, as Peter Cooper once said, that 'if a man will put away every day half what he makes, even if it be but 50 cents, he must of necessity in time become a rich man.'"

——GARDEN AND FOREST: "In a private letter, Mr. F. L. Temple, of Shady Hill Nurseries, now in Europe, states that the most interesting flowers he saw in England were the pyrethrums, and he was surprised to find that plants so little known and grown at home were, next to the rose, the most popular ones in English gardens in June. The best double varieties are as good as the finest China Asters in autumn, and they are admirable for cutting. Among the named single varieties, Melton and Mrs. Bateman Brown were noted as the best, while Captain Nares, Mont Blanc, Flora, Haggs & Schmidt and M. Barrall were among the finest double sorts."

——O. C. FARMER: "We know a merchant who carries a stock of goods worth not less than $10,000. If he is assessed a single penny he at once swears that he owes more than he is worth and the tax is promptly remitted. We know a farmer who recently bought a farm, paying $1,000 down, and mortgaging the farm for $4,000. He is assessed as if he owned the farm free and clear, though he is willing to swear that his debts exceed his assets and he could probably honestly do so. The dry-goods man escapes because, though he owns the goods, he owes for them. So it goes."

Hood's Sarsaparilla 100 Doses One Dollar

Warm Weather often causes extreme tired feeling and debility, and in the weakened condition of the system, diseases arising from impure blood are liable to appear. To gain strength, to overcome disease, and to purify, vitalize, and enrich the blood, take Hood's Sarsaparilla.

JOHNSON'S ANODYNE LINIMENT ESTABLISHED 1810.
For Internal and External Use.
Stops Pain, Cramps, Inflammation in body or limb, like magic. Cures Croup, Asthma, Colds, Catarrh, Cholera Morbus, Diarrhœa, Rheumatism, Neuralgia, Lame-back, Stiff Joints and Strains. Full particulars free. Price 35 cts. post-paid. I. S. JOHNSON & CO., Boston, Mass.

ENSILAGE
MACHINERY DEPOT.
A full and complete line, from the hand-machine up to the largest, of the **Smalley Cutters,** the **fastest cutting, strongest, most durable** and **best** ever built, including **Carriers,** both straight and angle, of any length required, and **Extras** and **Repairs** of all kinds, constantly on hand. Having the **exclusive** control and sale of these Cutters and all the appliances for the same, for all of the New England States and a large portion of the entire East, together with the right to sell in nearly all the Southern States, application for illustrated, descriptive and free pamphlet, showing **"why ensilage pays;"** and for free catalogue of both **Tread** and **Lever-powers, Threshers, Wood Saw-machines, Feed-mills** and **Fanning-mills,** should be made to the undersigned, proprietor of the old and reliable Empire Agricultural Works, over 30 years under the same management. **Agents wanted,** and **special prices given** for introducing in new localities. THE
RURAL NEW-YORKER.
A National Journal for Country and Suburban Homes.

Conducted by
ELBERT S. CARMAN.

Address
THE RURAL NEW-YORKER,
No. 34 PARK ROW, New York.

SATURDAY, AUGUST 10, 1889.

"POTATOES is gone" is the *verbatim* record of the opinion of one of the oldest farmers in the vicinity of the Rural Grounds.

THE R. N.-Y. hopes that all who speak of the sexes of strawberries will use the word "pistillate" to denote those varieties which have no stamens or imperfect stamens, and "bisexual" to denote those which have perfect flowers—*i. e.* both stamens and pistils.

AS THE older readers of the R. N.-Y. are aware, we have never favored planting pot-grown strawberry plants. If well grown, which is rarely the case, one may be assured of a fair crop the next season. Generally they are not well grown. The cost of expressage is outrageous. Buy layer-plants and set them out now.

AN appropriate name for the good, old Trumpet Vine would be "Humming bird Vine." These charming little birds seem to prefer its flowers to those of any other plant. We should want this old-time vine because it is so attractive to humming-birds, if for no other of many reasons why it should find a place in every garden.

AMONG many of Jones's new wheats we have raised the past year is Golden Cross, highly prized in parts of New York State The heads average three inches long, strongly bearded, brown chaff, medium-sized amber berry, two and three to a breast. Later we shall report as to the yield of a five-acre field of this wheat raised near the Rural Farm on Long Island.

Honey Sweet Corn (seed from J. J. H. Gregory and Johnson & Stokes), planted May 5th, was ready for the table July 27th. The tassels, silks and husks are usually purple. The plants grow a foot taller than those of the Crosby, and will average more ears to the stalk of about the same shape, size and number of rows, though the rows are not quite so close together or even. The quality is as sweet, we judge, as that of any variety, though we have not at this writing any of the later kinds for comparison. The objection to the Honey Sweet for market would be its purple husks.

IT is claimed that the price at which bananas are sold in this market regulates the price that can be obtained for other fruits. This is bad enough for the small-fruit growers in a season like the present when the foreign fruit is so largely imported. The consumers face a danger in the sale of over-ripe and decayed fruit. Day before yesterday a steamer arrived from Costa Rica with 8,000 bunches of overripe bananas. Inspectors of the City Board of Health seized the entire cargo and destroyed it. In spite of the vigilance of the officials, tons of decayed fruit are offered for sale.

A BOX of the new currant "Crandall" was received the past week from Frank Ford & Son, of Ravenna, Ohio. The branches were crowded with currants the largest of which were ten-sixteenth of an inch in diameter. The pictures of this currant can scarcely be said to be an exaggeration, except that the berries grow smaller towards the tip of the raceme. In flavor they are exactly the same as that of a Missouri Currant growing in the garden of the R. N. Y. The leaf is essentially the same, too, in shape though not so smooth. We do not see any reason for assuming that this is a hybrid.

THE publication of the photographic pictures to which the R. N.-Y. has frequently referred, will begin with our Fair Number. This new enterprise promises to be highly successful, and our readers may expect a treat. This Fair Number will be an excellent paper to show to your friends. The R. N.-Y. will send copies to all who may be interested in good farm literature. Send a list of your friends and neighbors. By the way, the R. N.-Y. offers special inducements to agents this year. Any person who can secure subscriptions can obtain permanent employment in the service of the R N.-Y.

THE R. N.-Y. again urges all who have occasion to talk or write about the sexes of strawberries to use the word "bisexual" (B.) to designate those varieties whose flowers are perfect, *i. e.*, bear both stamens and pistils, and "pistillate" (P.) to designate those which have flowers with imperfect stamens.

It is also well to bear in mind that the word "seedling" is properly applied only to the plant that is raised from the seed. Any plant propagated from it is not a seedling. To speak therefore of Brown's Seedling Strawberry or Brownell's Seedling Potato, when the original plant is not referred to, is absurd.

FOR an early corn for use just after Cory, Marblehead, etc., Crosby's Early is, in the R. N.-Y.'s estimation, unsurpassed. In moderately fertile soil, the stalks grow six feet high, measuring to the top of the tassel. The ears, generally two to a stalk, are borne a foot or more above the soil. The husks, like those of Stowell's Evergreen, are always of a fresh, light green. The ears, about eight inches long and from 10 to 12 rows, taper from the but to the tip. The rows are close together, and straight and the kernels of uniform size. The quality is equal to that of the Concord. Planted May 5th, the first ears were mature July 25th.

THE R. N.-Y. asked its friends to tell us how many head of stock they keep. The purpose was to make some comparisons with the farmers at Cranbury, N. J., who seem to be going out of stock keeping. Here is one of the first responses. Let us have others:—

"My farm comprises 57 acres, including wood land and pasture. My stock consists of five horses, one colt, 11 cows, a three-year-old bull and 10 head of young cattle. I wintered 28 head of horses and cattle, and keep four horses and a bull in the barn throughout the summer. I have not built a silo but propose doing so next year."

E. L. BASS, Secretary Vermont Dairymen's Association.

DR. HOSKINS sent to the R. N.-Y. last spring a few kernels of what he calls Extra-early Black Mexican Corn, produced by crossing the Blue Squaw of Dakota and Hoskins's Early Dean, claiming that it is as sweet as the Mexican and as early as the Cory. The few kernels were planted May 5 beside Crosby's Early planted the same day. The first lot was eaten July 22, about one week before Crosby's was ready. The plants in poorish soil grow less than five feet high. The ears are borne just above the soil, one, two and sometimes three to a plant. The ears average about eight inches long, eight rows. The quality was found to be much the same as that of the late Mexican. There is, however, the same objection to the new variety, viz: the cobs and kernels turn to a dull, dark color after being boiled.

THE following note touches a matter that the R. N.-Y. has alway deemed very important. Now is the time to attend to it.

"In every large flock during the summer months, there are always some sheep that do not keep in as good condition as the rest, and there are nearly always more or less cull lambs. Every sheep-grower should have a small inclosure where he can place these culls with their dams, and give them a little grain every day to help out the grass and milk ration. A mixture of corn-meal and bran, equal parts, is a very good feed for these ewes and lambs, and it is within reach of most farmers Of course, to do this gives some trouble; but I think the farmer will be well repaid as well as surprised when winter comes and he finds these sheep as good as any in the flock. To secure an even lot of sheep should be the farmer's aim, and they can be made and kept so by proper care and feed."

IN the City Hall Park in this city is a circular stone basin 20 or 25 feet in diameter. In it are a number of aquatic plants now in full bloom, and the effect is charming. The white water-lilies, with their floating green leaves, remind one of many similar flowers gathered in our inland rivers and lakes in former picnic-times. Then there are the Amazonians looking, for all the world, like immense buttercups out of their proper sphere. The Zanzibar Lily nestles its large, sky-blue flowers under the shade of the stately Indian Lotus, which rears its rosy-colored flowers high above its neighbors. While not every farmer could afford a pond of this kind, there are but few who could not have at least a tub or half-barrel sunk in the ground in which a few of our common water lilies would thrive with an occasional pail of water thrown in to renew the supply. This is a flower that never looks half so charming as when growing in its native element.

SPECIAL NOTICE.

IN reply to inquiries we may state that the inner portion of the flowers of the potato R. N.-Y. No. 2 is a light purple. This purplish color covers irregularly about *half* the corolla. The outer portion is nearly white. The proportion

of white and purple is shown in the illustration which was carefully drawn from nature. This variety *never bears solid white* flowers. The stems also are, here and there, *tinted* with purple. They are long-jointed and branch less freely than do most other varieties.

HONEY BEES IN COURT.

A CASE of considerable interest to bee-keepers was recently tried by the Supreme Court of the Fourth Judicial Department of New York State. The questions passed upon were substantially the following:

1. May the honey bee become an unlawful trespasser and a nuisance?
2. If so, can the owner of the offending swarm be held amenable in damages to the injured party?

Here is the reported history of the case. In 1887 a wealthy banker of Delaware County, N. Y., had a neighbor who kept an apiary of 20 swarms of bees within 50 feet of the banker's dwelling. The banker complained that the bees attacked and stung members of his family—that they were, in fact, vicious and offensive insects annoying his horses and other stock. The neighbor refused to remove the bees and the banker began a suit for $1,200 damages and an order for the removal of the bees. The National Bee Keepers' Association assumed the defense and thus made this a test case. The trial lasted several days and brought out much expert testimony. The jury declared the apiary a nuisance and awarded the plaintiff six cents and costs, thus establishing a precedent. The court at once issued an injunction restraining the defendant from maintaining the apiary on his premises. The defendant appealed and is now again defeated. It is said that the Bee-Keepers' Association will continue the fight by a further appeal to the Court of Appeals—the court of final resort.

THE PURITANS.

WE are making history at such a rapid pace in these days that some of us hardly realize the thoughtful significance of the recent celebration at Plymouth, Mass. Public monuments are dedicated every week. The history of this country has been a stirring one, packed full of incidents that seem to call for a substantial token of remembrance. There is nothing, however, in the history of this nation, or, in fact, in the history of any other nation, that has had more to do with the making of history than the landing of the Pilgrims at Plymouth.

Suppose those stern, determined men had gone to some Southern harbor. The entire history of the country would have been changed. New England would never have gained the supremacy she ably maintained for so long. The great West would never have been cut out of the rough by the descendants of the Pilgrims. The Pilgrims themselves doubtless owed much of their strength of character and body to the fact that they were cast upon a bleak country where the closest economy and energy were needed to preserve life. In a more favored section they might have lost that rugged strength and simplicity that gave them their peculiar power.

We owe much to Puritanism. The original Puritan was an honest man standing like a stone wall for what he considered right and fair. He has been called a bigot, a narrow minded, obstinate fellow who constituted himself as sole judge and jury and never changed his mind. He suited his time, however, and some of his principles and practices might well be revived in this age. About 250 years ago a Cape Cod man was appointed to watch for whales. He made a false report, saying he saw a whale when none was within sight. For this lie he was fined a sum of money that would amount in this age to nearly $500. Who says this punishment of liars would be out of place now? If old Miles Standish or Governor Bradford could come back today and see how we "run things," no doubt they would feel that much of their labor was thrown away. It would take them a long time to become reconciled to our "deals" and "combines." Old Miles was a man who never dodged a responsibility. When a hostile Indian sent him a snake's skin filled with arrows as a token of defiance, the old fellow filled the skin with powder and shot and sent it back. If the stout old soldier lived in these days he would answer the attacks upon popular freedom in the same spirit.

BREVITIES.

FLOODS.

BEDRAGGLED.

SWEET CORN is a trifle lower again.

POTATO vines, those of both early and late kinds, are dying.

THE blackberry crop is probably as great as any ever raised in the northern States.

DURING the last four days (July 31) there have been 3.51 inches of rain at the Rural Grounds.

ONE result of the heavy rains is that bricks will be higher; many half-burned bricks were destroyed.

A COMPOSITOR makes it *Shapeless* instead of Sharpless Strawberry. Some specimens would seem to warrant this.

EDITOR C. A. DANA forcibly sets forth the claims of the sun-flower as the fittest among the national flower candidates.

ALL who are interested in vegetable growing should read William Falconer's article on page 529. You can not find such information in books.

ABOUT the only living creatures capable of doing a full days work during the storm were the potato beetles. They never stopped but ate, and grew fat.

LIMA Bean growers are hopeful for good prices all through the season. The rains have washed out many fields of beans so badly that the yield will be quite seriously curtailed.

IT seems evident that the storm has injured the potato crop quite seriously. Potatoes ought to bring a good price this year. The corn crop has also suffered and the grain will be high.

E. WILLIAMS says, on page 522, that strawberries should be consumed within 36 hours at furthest after being picked. To suit the writer's taste, this time should be reduced to as near one hour as possible.

FROGS' legs find a ready sale in the New York markets. The present price is 25 cents per pound. The R. N.-Y. has had so many letters from those who want to know how to raise, prepare and sell this article of food, that we propose to make it the subject for a special article.

NO GAMBLING devices, side-shows or anything which might exert a demoralizing influence upon the young or old will be permitted at the New York State Fair to commence September 12 and close the 19th. We are promised by Secretary Woodward and the Executive Committee an absolutely "clean" fair.

A SUBSCRIBER who read the articles entitled "Is Cream, Cream," writes:—

"I found out what I wanted. And the point is just this; can a man, five 'spaces' of whose cream will make a pound of butter, afford to be a patron of a co-operative creamery where it takes 6½ spaces of the mixed cream to make a pound of butter?"

RAINS incessant—the rainiest season ever experienced within the remembrance of the farmers in this part of the country. The R. N.-Y. anticipated a very dry season because the rainfall for the past two years has been excessive. All the more shall we count upon excessive droughts in the near future. This is not in the way of a prediction at all—the R N.-Y. as a weather forecaster owns up that it is in disgrace—but merely as the result of a bit of *a priori* reasoning.

The Garden.

THE VEGETABLE GARDEN.

WILLIAM FALCONER.

CELERY.—I sowed our main crop out-of-doors on April 25th. Just as the seed was bursting its shell in May, we had moist weather, then a parching hot spell, and not a plant came up, every seed was wasted in the ground; so I had to resow, which I did on May 24th. This may seem very late to many growers, but it isn't, for I now have splendid plants, six inches high, and all transplanted into seed-beds. They are in time enough, for we have very little ground ready for them yet. We plant them after peas, early potatoes, onions or strawberries. The great thing with celery is to keep the plant in vigorous growth from the moment the seedlings appear till you store away the plants for winter. Don't let them get spindled by overcrowding, checked by drought, or stunted by starvation. Early celery has been set out in trenches three feet apart. This closeness is because we must blanch it with boards rather than with earth, to prevent rusting. Our early main crop was planted in rows 4½ feet apart, and our late main crops three feet for single, and four feet for double rows. For celery we manure abundantly and broadcast in fall; crop with peas or something else in spring, then in July or early August throw out our rows for the celery; the rows are six inches deep and into them a heavy dressing of fine manure is worked. The level system is not so good for us as is the trench plan. By planting in shallow trenches we use the ridge for spinach, lettuce or other catch crops, as well as for walking when watering the celery in dry weather.

SNAP BEANS.—I sow these wherever a vacancy occurs, and I am not particular about giving them regular rotation ground. They will grow in land too sour for peas or cauliflowers and too shady for root crops; and I will sow them every week till September. The last sowings will be of the White Flageolet, which although a poor bean, is dwarf, free-cropping and very early, and I can cover it easily with frames and sashes. The best of all green-podded snap beans is the Valentine, and of pole beans, Dreer's Lima. The Valentines we are now using were sown May 28th. Our earliest Valentines were sown April 11th. At that time I put in a large sowing, part for use and part for seed. The seed is now ripe, the vines gathered and spread out to dry, and the ground forked over and planted with Savoys. The seed now saved is what I shall use for August sowings.

LIMA BEANS were sowed early (May 6) because the season was early. We have a piece of filled-in land which is rich, level and moderately moist, but for some unknown reason every crop—melons, celery, cauliflower, etc.—except beans, I ever tried in it, failed; but beans grow superbly in it, and I use it year after year for Limas, and every succeeding year they seem to wax stronger; but there is no stint of manure. Note a curious point in sowing; one man sowed the seed by pushing it into the ground, eye down, and every seed grew; another sowed by laying the seed flat and covering one lot loosely, and the other lot by tamping the soil firmly on top of the beans. The firmly-tamped ones grew as well as the eye-down ones; whereas the loosely covered ones nearly all rotted. I have tried all the recorded devices for training Limas, also shortening in the vines at various times, and now unhesitatingly assert that the common method of using poles and letting the vines climb up them at will is, in my opinion, the best and least troublesome, and no amount of pinching ever gained one day in earliness.

THE DWARF LIMAS.—Now let me "speak out in meeting." I do not know, never did know, and cannot perceive what advantage we have in dwarfing the Lima. The dwarf yields no better fruit; its cropping capacity is vastly curtailed; in earliness I find it has no advantage over the vine, and its convenience as a garden crop is open to question. I certainly regard the vine as the most convenient. Among the poles we can walk around every hill in picking the beans; after the end of June the pole beans have got beyond the power of the weeds and will choke the weeds to death; but the dwarfs are at the mercy of the weeds so long as the beans live. Of course, we shouldn't have weeds in the garden, that's very true; but we don't always practice what we ought. The poles are easily placed, easily kept and last for years—that bugaboo won't scare practical people.

HENDERSON'S DWARF LIMA is a dwarf Sieva. In time of flowering and podding it is exactly the same as the common Sieva, and about 10 days ahead of the large Lima. Our plants sown May 17, are 15 to 18 inches high, very bushy and full of flower spikes; in several cases there are over 20 pods to a spike. It displays no inclination whatever to run, but is in reality a fixed dwarf. The chief use I have always had for Sieva Beans was to fill the gap between peas and large Limas; that is, to come in from the 20th to the 25th of July till the 1st or 7th of August. So long as I have plenty of peas no one wants Sievas, and as soon as large Limas come in the demand for Sievas ceases.

KUMERLE'S DWARF LIMA, FROM THORBURN.—In this we have a veritable dwarf form of the large Lima, dwarfer, if anything, than the dwarf Sieva, perfectly fixed in habit and with no inclination whatever to run. It is very free-flowering. Ours were sown May 17, and are now full of blossoms, but very few pods are set yet. It is so much of a stranger to me that I know nothing further about it, but I do wonder why so decided a novelty was not more prominently advertised.

PEAS—LATE PLANTING.—On June 3, I sowed Advancer, Abundance, Blue Beauty, Stratagem, Yorkshire Hero, and Midsummer in rows three feet apart. Blue Beauty gave us our first picking on July 12, and is very prolific. Advancer came on the 15, and, although doing well, is not nearly so full as was the Beauty. The others are not ready yet (July 19). Between these rows on July 13, I sowed Squantum Corn. It is now an inch above the ground. The peas don't shade it, and they will be off before it hurts them. On April 10, I sowed 21 kinds of peas for trial. In due time we picked from these for use and let the rest ripen up for seed. About a week ago I cleared them all off, and am now preparing the ground for celery. I always try to keep up a succession of peas till Lima Beans come in about the first of August, but it hardly pays, for after the 20th of July, mildew generally ravages the crop and they are of poor quality. I had good success with peas in the melon ground. I marked off the ground in rows seven feet apart and sowed the melons and between every second and third row of melons sowed a row of peas. These peas have yielded their crop and are now ready to be cleared off. The place where they ran will be occupied as pathways in the melon beds. This has been a good year for peas. Alpha, Champion of England and Yorkshire Hero are unexcelled for quality. Most of the new-comers are failures in this respect.

THE TURNIPS we are now using were sown May 28 and are Purple-top White Globe. We sow a little every two weeks till the end of August, for succession. All sowings made before August get very wormy in our light, heavily-manured land.

THE CUCUMBERS we are now using were sown May 25. They are the market gardeners' strain of White Spine, given me by Silas Albertson of Roslyn, and extra fine. We sow a little every fortnight. Old plants don't last long. For pickling, dig out every second row of early potatoes and in their place sow cucumbers. A nice sowing of cucumbers may be put in in August, but somewhere where a frame may be put over them in the fall to prolong their fruiting season, and one must be ready with lots of tobacco stems to put about them, as late cucumbers are much subject to lice pests.

ONIONS have done well. Large Red Wethersfield, Yellow Danvers and Southport White Globe are our main crop. Mammoth Pompeii promises well: it is a large oval onion; but for general purposes I find nothing better than the three first mentioned. For a few years back our onions have been much troubled with the onion-maggot at the roots in May, so this year I changed the patch to across the road—only about 20 feet away—and not a maggot was found; but with July came leaf-thrips, and from this pest we have no immunity. It never completely ruins a crop, as it does not appear till July, by which time the onions are half grown; but it sadly affects the longevity and large size of the crop. About the first of August our onions will be ripe and pulled and the ground will be ready for strawberries or celery.

ONIONS FROM SETS were gathered three weeks ago. They swell up and ripen quickly. The chief point about them for family use is that they come in early and can be grown well enough in light sandy land, whereas seed onions should always have good ground.

But "set" onions are poorer keepers than are "seed" onions, so a few of them are sufficient for a family.

POTATO ONIONS have behaved badly, and they have done this for the past three years. They fail to start and keep up vigorously; they "melt off" as it were. So far as flavor goes they are poor onions, but when they do well, they are a very certain crop, and the onions are large, of fine appearance, and are capital keepers. We harvested ours 10 days ago.

SHALLOTS I gathered a week ago, and they now are spread out to cure. Never were they finer. This is on account of so much rain. They are used whole, and are much sought for by French cooks. They keep well during winter, and are good stock to have, as they don't trouble us with sprouting with every warm turn of the weather. They multiply greatly.

GARLIC is not quite ripe yet; we let it stay in the ground till the necks bend over, then lift and cure, and hang up in bunches. It is very hardy. It is a good deal asked for by French cooks for flavoring, and really for ordinary domestic purposes I think we can get along very well without it. It is the "loudest" of all the onion race.

CHIVES are a nice thing to have. They are hardy, reproductive and neat, and so useful for soups and salads. The tops only are used. Cut over a few plants every now and again to have them come up fresh and green.

LEEKS we sowed on April 4, and left them in the seed rows till a week ago, when we lifted them, cut them hard back, tops and roots, and planted them out in rows 18 inches apart and six inches asunder in the row. A few of them are enough for a family. They are nice for soups, but if one has onions, leeks are seldom asked for. They are a very accommodating crop. No matter how early they are sown, they will not "bolt" to flower that year, and you can keep them in the seed row till you have convenient ground or time for planting them out. What is known as the Large American Flag is a very satisfactory kind. Get fresh seed every year, for old seed is worthless.

Queens County, Long Island.

PERFECT-LEAVED STRAWBERRIES.

PROF. J. L. BUDD.

The Downer Prolific Strawberry; varieties for Iowa; influence of "breed" in strawberries; offspring of Chili crosses with indigenous Western species best for dry interior regions; superiority of American strawberries throughout the North Temperate zone; vitality and perfect foliage to be henceforth the paramount objects in strawberry "breeding."

A "BREVITY" in the RURAL states that I "deem Downer's Prolific the best strawberry for home use." I have said that on our grounds the Downer was the best variety to use as a fertilizer for the Crescent for home use, and that it would prove the best fertilizer for market if the Downer were better in color. But this remark will not apply to all parts of the country, or even to all parts of Iowa. On our rich, black drift soil nearly all the popular varieties of the States east of the lakes fail wholly or partially on account of sunburn or rust of foliage, yet we have several excellent sorts that prove defiant to wind and weather. Notable among these are four varieties originated by J. S. Downer, of Kentucky, viz: Downer's Prolific, Green's Prolific, Charles Downing and Kentucky. The Crescent, Great Pacific, Bubach and a few others have this perfect foliage, while scores of varieties that do well on other soils and in other parts of our great domain fail to stand our extremes of summer.

"IT IS IN THE BREED."

In speaking of the reasons why some of his varieties were perfect in foliage, Mr. Downer said, several years prior to his death: "It is in the breed." Sir Henry Vilmorin has made about the same remark in regard to the strawberries that maintain perfect foliage on the interior steppes of Russia.

As the history of our best strawberries has not recently been discussed, it may be useful to indicate briefly what Downer and Vilmorin meant by "the breed" of perfect-foliaged sorts. They believed—as does the writer—that the best strawberries for the dry interior climates of both continents have come from crosses of the Chili species with the indigenous species of the West known as Fragaria Illinoiensis or F. Iowensis. On the other hand, many of the choice varieties which fail with us are derived from crosses of the Chili species with that of Virginia (F. Virginiana). While such general statements are difficult to prove in a direct way from the recorded statements of books and periodicals, the history of such advances as Keen's seedling, Hovey's seedling, Downer's seedlings, and Vilmorin's seedlings, confirms the belief in an indirect way.

Our people seem to have forgotten that the best strawberries of the North Temperate zone to-day, are purely American. So far as I know, the indigenous species of Europe and Asia have not given a single variety now considered valuable for general culture in any country. At a very early day the American species from North and South America were introduced into Europe and Asia, and their crosses are now found at the extreme east limits of Europe, and I have been assured that they are grown in Persia, Central Asia, and China.

As we have probably about reached the limit of development as to size and quality, and the value of new varieties largely hinges on the vitality and foliage of the plant, it is about time that another Downer should go back to first principles. The best varieties of the Chili Strawberry are now obtainable, and Iowa and Illinois have perfect-foliaged native sorts with fair size, *and the unapproachable flavor*, which the big South Americans lack. We should have system and method in plant as well as in animal breeding.

Ames, Iowa.

Sheep Husbandry.

SHEEP AT THE ROYAL SHOW.

HENRY STEWART.

"Golden-hoof" a prime favorite in England; numerous breeds at the show; the most useful, the most popular; heavy long-wools losing favor; the Shropshire ahead; Down, Leicester, Lincoln and Cotswold, Romney Marsh, Dorset Horned, Welsh Mountain, Cheviot, Roscommon and other less notable breeds.

THE report of the grand exhibition of the Royal Agricultural Society of England is full of interest and instruction to American farmers, but to me the sheep show is particularly interesting, not only in a personal way, but as affording an exemplary lesson to American farmers of what might be done in this country, were equally deserved attention given to this most profitable of all farm stock. Considering the narrow boundaries of the little island, having only little more acreage than the State of New York, the large variety of sheep kept is truly amazing, and shows how much the sheep quickly becomes acclimated to its conditions and how even small differences in climate, soil, and conditions of agriculture affect in a most important manner this kind of farm stock. At this show the following breeds were exhibited all in respectable numbers, and of course in the finest condition: Leicesters, Border Leicesters, Cotswolds, Lincolns, Oxford Downs, Shropshires, South Downs, Hampshire Downs, Suffolks, Dorset Horned, Romney Marsh, Devon Longwools, Ryelands, Dartmoors, Exmoors, Wensleydales, Roscommon (Irish), Limestones, Cheviots, Black-faced Scotch, Lonks, Welsh Mountain, South Hams, St. Kildas (one of the Scotch island breeds), Merino, Dorset Downs and Portland. Among the foreign breeds were Zulus, and the African long-tailed sheep.

Every one of these breeds has some special interest. As showing the tendency of English sheep culture to the more commonly useful kinds and to the neglect of the special breeds noted for some singular points of value, the numbers of the entries are significant. Thus the Shropshires made 212 entries; the South Downs 123; Oxford Downs 82; Hampshire Downs 31. All of these are of the Down class, of which the Shropshires have gone far ahead even of the old favorite South Down, and well it merits the favor into which it has sprung as the best mutton and domestic wool sheep of all the breeds. The longwools which were a few years ago in the ascendant, have gone back, the great, fat carcasses having gone out of fashion and having been found unprofitable in the present period of cheap products, in competition with the meat-making and clothing-wool-producing Down breeds. Several years ago, after a patient trial with the Leicesters and Cotswolds, I gave them up as unprofitable sheep and have since constantly advised farmers—these are farmers' sheep and not shepherds'—to let these heavy-bodied, much-eating, long-wooled sheep alone, and the English farmers have at last found it out in spite of their strong conservatism. Only seven of the big Lincoln sheep and 11 Leicesters were on exhibition at the Royal Show; and the formerly extremely popular Cotswolds showed only 60 entries, which was less than twice as many as the Romney Marsh breed which had 36 entries.

This Romney Marsh sheep is kept on the salt meadows of the southeast coast of England and is the only existing sheep which can

stand a wet foot and marsh pastures. It is a coarse animal, having coarse, long wool, valuable for special uses, but a good mutton carcass. No doubt it would find a useful place here, as the Down breeds have under the special conditions for which they are fitted. There were 31 entries of the Dorset Horned sheep, a breed which has lambs twice a year and of which some importations have been made here. This sheep is exactly fitted for dairy farms where early lambs can be disposed of, and a carcass of mutton can be divided up easily among neighbors; but it is a sheep having but one purpose, good for lambs, but poor for mutton and wool, and it will never make a popular sheep or a profitable one here.

The 34 entries of Welsh Mountain sheep are noteworthy as showing the popularity of a good sheep in the right place. Elsewhere but on its native rocky, but sweet nutritious pastures, this sheep would be of no account unless it could change its character with its environments and improve with them. In its place it is one of the most valuable sheep. Small, active, able to outrun a fox or wolf, with fine wool, especially useful for flannels—the Welsh flannel is pre-eminent among housewives—and most delicious but very small mutton, it is a conspicuous example of the survival of the fittest. This sheep would do well in many localities where the land is now lying useless, as in the Pennsylvania mountain regions; parts of New England, and especially in the Southern mountain region. This is called a small sheep, but only as compared with the 400 or 450-pound Lincolns, for a prize ram—winner of the 3rd prize only—weighed 190 pounds. I have seen a hind-quarter of Welsh mutton and helped to eat it, which weighed only six pounds; but the morsel was preferable to the 50-pound mass of a tallowy prize Lincoln. Some sheep of quite unknown character here were the Ryelands, Dartmoors, Exmoors, Devon long-wools and South Hams, all useful sheep for ordinary purposes and of local reputation only. The Wensleydale, a mountain sheep of northern England (Westmoreland), has a blue face, is an excellent mutton and wool sheep and hardy and able to rough it in the storms of summer as well as of winter, which sweep the bare sides of the Westmoreland mountains. The Lonks are large sheep of local reputation in the mountains. A related breed of mountain sheep, much more popular than this—the Herdricks—were conspicuous by their absence. Both of these sheep have some special valuable points as have the black sheep of St. Hilda Of these the fine wool useful for particular domestic uses, as for such soft fabrics as shawls, comforters, and other knitted goods, is the produce. The Scotch sheep, the Cheviots and black-faced breeds, have been tried here; but do not make their way very well. These sheep cannot withstand our hot sun and heavy rains. Their native mists and cool climate suit them, and they come to perfection on the succulent pastures always dripping—with dew—it may be called, as the rain there is mostly mist, a gentle distillation from the clouds and fogs. The Irish Roscommon is the sheep which makes up those enormous droves that are seen at the fairs so common to that verdant isle. At Donnybrook, the principal of these fairs, there are usually 100,000 sheep gathered for sale and the Roscommon sheep is the type upon which all Irish sheep are based, an excellent farm sheep, of good size and bearing useful wool of which the everlasting Irish frieze is made.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

A GIRL who cannot sew certainly loses one of the most womanly of all pleasures. Any girl in moderate circumstances who cannot make and mend all her own clothing, to say nothing of making and mending household linen, is certainly imperfectly educated. We have seen a young mother in very moderate circumstances compelled to put all her sewing out, because she had never even learned enough to make a baby's petticoat. To most mothers it is such a pleasure to sew for their little ones—to plan and devise all sorts of dainty garments. One proficient in hemstitching, feather-stitching and smocking can contrive the daintiest garments, and materially lessen their cost.

* * *

But it is not in fancy sewing only one should strive to excel. What a field for ingenuity may be found in making over garments. We have seen so many gowns that were prettier after being made over than when they were new, that we are prepared for all sorts of wonders in this line. The most exasperating thing about making over is to find oneself short of some material and when in the midst of the work. It is the best plan, when ripping apart, to promptly put useless pieces into the rag-bag, and then decide at once what must be had in the way of new goods. It does not pay to use shabby finishings and limp linings; a made-over must be well sewn, with every detail exact. Sometimes we use old linings in wash dresses, but we find it poor economy.

* * *

SOME pretty English bed-covers for a spare room were made large enough to cover pillows and all; they were of sheer white muslins with a wide hemstitched tuck, through which was run a pink ribbon. It was lined with pink sateen, and bordered with a muslin frill nine inches deep: A handsome linen cover had a deep border of turkey red twill, worked in a beautiful pattern with white silk. Above and below the border threads had been drawn in the linen making a pattern in drawn work. It was edged with red and white fringe.

"MOTHER BOYS."

MRS. JAMES STEEDMAN.

"HOW can they bear the loss, they were such mother boys," we said among ourselves when word came that a dear mother had been called from earth, leaving three sons just standing on the threshold of manhood. A week later walking home from Sabbath evening service with an aged aunt, we talked together of the sudden death, and aunt said, in almost the self-same words that had passed around our family circle: "How they will miss her! They were such mother boys." The words kept by me, as parting I wended my homeward way. And it seemed to me that had I been a stranger listening they would have explained the mother's character so well, for we are told the children love best the mother who governs wisely and well, mingling judgment with tender love in her care for them, refusing often when she longs to grant the privilege they ask, standing firmly between them and the temptations they would throw themselves among. Unthinking, unknowing youth! How oft it tries the mother heart! Bent only on the pleasure of the moment, it chafes and galls at the restraining hand of love.

Nature had bestowed a full measure of health, and strength, upon this mother, and most faithfully did she use the gifts, filling well her place in life, the center of a happy home. While there were still a score of years to look forward to, until she should in the course of nature have filled up the measure of allotted days, suddenly and without warning the message came, and, obedient as in life she answered: "Even so Lord."

Husband and sons brought their loved one to her childhood home at the foot of Schunnemunk. And in the quiet grave-yard, lying in the shadow of the grand old mountain, they laid the wife and mother to rest.

AMUSEMENTS FOR A RAINY TIME.

PEARL.

TO amuse yourself and one or two very intimate girl acquaintances, get the one nearest your own hight and style to try on, one after another, all your dresses, hats and wraps, and then do the same for her. You will be apt to wear those clothes with largely increased satisfaction after seeing for yourself just how they look "on." I don't dare to breathe a suspicion that you may also discover a stitch wanting somewhere, or that a frayed braid or lining might reveal itself in such a "dress parade," but I do venture to suggest that such times afford beautiful opportunities to plan alterations, where they are desirable.

* * *

But, Docia Dykens, why try only to "appear pleasant and agreeable?" Be so, truly within, and you need never again seek for relief from *ennui*. You are your own most constant and confidential companion; it is well worth while to train that companion who is "yours to command," into a pleasant and profitable one.

How?—By teaching her to think. Hold your thoughts steadily to a given subject for a certain length of time. Compel Docia D. also to learn to feel with and for others, and, my word for it, the world will soon find plenty to occupy you, rainy days and all. It's not really amusing at all times and all through life thinking and feeling with and for others, but it is so intensely interesting as to lift one quite above the need of amusement. And a loving sympathizer has no need to try to "appear" nice in order to be appreciated; she is as precious as gold to all who have been blessed with her sweet ministry.

What do I do on rainy days? Seek out some forlorn creature and devote myself to her or him—as the case may be—with all the assiduity of which I am capable. But, you see, I belong to the "Soul-Winner's League," and would rather lead some one "out of darkness into light" than be the center of an admiring group. Tastes differ; duties also; but to all will come the words: "Inasmuch as ye did it (or did it not) unto others, ye did it unto ME."

A WRITTEN SERMON.

AUNTIE.

HOW grand it is to be God's minister! to speak to our fellows in a name that commands respect for whatever we utter! Since women are not called to the pulpit—as a rule—they ought not to sermonize, yet for once I cannot resist the temptation to try: the text is so perfectly suited to what I want to say and I want so much to make a lasting impression.

"She will do him good, and not evil, all the days of her life."

This is a part of King Solomon's word-painting of the ideal woman, to be found in the thirty-first chapter of the Book of Proverbs, in the twelfth verse.

The expression means that "she" will do "him" good, only and unmixed good, always. It is not so long since there issued from the press a story bearing the very appropriate title of "She." To me it was worth the odd minutes given to its swift perusal, but I could not profitably have bestowed upon it any more time than I did; so, also, many a man's wife, worth all she cost him to woo and win, and maintain afterwards, is yet worth *no more*. Why no more?

Gentlemen, yours is the inalienable right to measure woman by the Scripture standard: if "she," whether wife, mother, sister, daughter, sweetheart or friend, does *you* "good and not evil" whenever you are in her company, it is well; if otherwise, beware!—Often some woman who is devoid of beauty, aged and an invalid is eagerly sought out by old and young men, and appreciated to a most flattering extent, because she is true to the scripture ideal, doing them good.

So, my dear lady reader, yours must be exceptional circumstances indeed, if there be not within reach of your best influence some masculine; and I boldly draw from my text the inference that, being a virtuous woman, you must, can, and will "do 'him' good and not evil," be he husband or father, brother or son, lover most dear, or a mere hired servant. Consider, then, in the case of every man, and, particularly if you are a wife, in the matter of your own husband, this thing of "doing him good."

God created Eve to do Adam good—a queenly mission, worthy of the woman whom God's own hand had fashioned for this work. How terribly she fell when the Evil One caused her to do him evil instead, and how many of her daughters fell with her! God made us to be "a help-meet,"—a suitable help—wherever and whenever help is most needed by man. Are you this to your husband, dear madam? Are you this to your lover, maiden fair to look upon? Are you this to friend, son, acquaintance, employé, stranger whom you chance to meet, oh woman to whom the Lord God has given the command and the power to be needed help on the upward climb?

GOLDEN GRAINS.

THE SUNDAY SCHOOL TIMES says that we should hope for the time when the overdressed young woman, with one of Ouida's novels in her hand and a dead bird's wing on her empty head, may disappear along with the male peripatetic who calls it sport to silence a throatful of melody with a bang of a hateful gun.....

If we would win others to the right, we must show that we are in love with the right, and that, however we hate the wrong, we have no feelings but those of loving kindness for the wrong-doer, whom our Saviour loves, for so, and only so, can the same mind show itself in us which shows itself in the Lord Jesus.....

Ill fares the land to hastening ills a prey,
Where wealth accumulates and men decay;
Princes and lords may flourish, or may fade:
A breath can make them, as a breath has made;
But a bold peasantry, their country's pride,
When once destroyed can never be supplied.
Goldsmith.

Few sentences have set people to thinking as the statement made by Bishop Potter in his famous sermon in St. Paul's Church: "We have exchanged," said he, "the Washingtonian dignity for the Jeffersonian simplicity, which was, in truth, only another name for the Jacksonian vulgarity, and what have we got in exchange for it? In the older States and dynasties they had the trappings of royalty and the pomp and splendor of the king's person to fill men's hearts with loyalty. Well, we have dispensed with the old titular dignities. Let us take care that we do not part with that tremendous force for which they stood! If there be not titular royalty all the more need is there for personal royalty. If there is to be no nobility of descent, all the more indispensable is it that there should be nobility of ascent—a character in them that bear rule so fine and high and pure that as men come within the circle of its influence they involuntarily pay homage to that which is the one pre-eminent distinction, the royalty of virtue!".....

THE Rev. Dr. Archibald Alexander, of Princeton Theological Seminary, was a very learned man, but exceedingly plain in his language. He knew how essential simplicity was to clearness and force. There was a schoolhouse in the vicinity, where the students held religious services and aired their eloquence. An old colored man attended every Sabbath, but the students talked so far above his comprehension that he remembered little of the sermons and understood less. But one Sunday afternoon Dr. Alexander preached. The old colored man was both delighted and instructed, and made the following comment: "A poor, unlarnt ole man, jist like myself, preached. I don' know who he was, and didn't s'pose he was hardly fit to preach. But I'm glad I went, for I can remember everything he said." In this criticism was hidden a compliment of the highest order.....

GEO. WM. CURTIS spoke at Gettysburg of the dangers of our immigration laws; He said it must be insisted more and more strenuously that it is not so much immigration that constitutes our peril, as the way in which we handle our immigrants. If we would inform them frankly that the civilization into which we receive them is a Christian civilization, maintain over them kindly but firmly the restraints of righteous law, abolish the saloon, forbid the desecration of the Sabbath, welcome their children to a school with the Bible in it, and thus quicken and intensify the assimilating forces of our national life, we should greatly reduce the danger from this source. Mere restrictions on the volume of immigration are not the safeguards against the peril it involves, but a healthier and more robust national Christianity. The evil is a moral and spiritual one and it demands a moral and spiritual cure.....

Domestic Economy

CONDUCTED BY MRS. AGNES E. M. CARMAN.

If we were asked to define, in the fewest words possible, the word "economy," we should say: "That way of living which secures the greatest amount of happiness." That man or woman who has passed the happiest life has been, in the broad sense of the word, the most economical.

EXTRACTS FROM SUNDAY EVENING TALKS AT THE RURAL GROUNDS.

IF you desire to do good in this world, be true to all with whom you have relations. Praise your friends *heartily*. Serve them with all your soul when you can, and *don't* feel that God wants you to go rummaging through their pockets to find out whether they have not stolen from you; or through their hearts to find if they are PRECISELY in the right place. Bear in mind every hour that we are choke-full of erring propensities; that it is human to err, that it is divine to forget and forgive. The spirit of real friendship will never countenance a disposition needlessly to dwell upon shortcomings and frailties—not that it would shut its eyes thereto, but that it loves the *more* to dwell upon the nobler impulses of the heart.

Miscellaneous Advertising.

When Baby was sick, we gave her Castoria.
When she was a Child, she cried for Castoria.
When she became Miss, she clung to Castoria.
When she had Children, she gave them Castoria.

Let us praise *thoroughly* when we can; let us serve a friend in good faith or not at all. If we can utter no words of praise sincerely, let us keep our mouths shut unless it be a plain duty to condemn what is absolutely condemnable. *Then* let our condemnation be as sincere and outspoken as was our praise. But don't *mix* them. You can't have your pie and eat it too. He who is not for me is against me. Cheap friendship is a *fraud*. It reminds me of a man who sets himself up for a "*gentleman*" and who demands consideration as such while he isn't self-sacrificing enough to control his tobacco-chewing fondness in the presence of ladies.

* * *

ONE of the most cowardly things a man or woman can do is that of seeking to injure a person while he seems to praise him. It is the method employed by hypocrites, Wall Street speculators, lawyers and politicians to damn and yet escape the penalty of damning. It is the method of selfish friends to retain friendship without in turn making any of the sacrifices which the word friendship implies. Did it ever occur to you that the very basis of *real* friendship is founded in the desire of either to *benefit* the other? Too often so-called friendship is based upon the desire of one to help himself at the *cost* of the other.

* * *

BE sure if you would judge human nature astutely, that the happy face comes from a good heart, and that the sour face with its down-drawn lines, the wicked eye, the hard, cruel expression are true indices of evils that result from a life that has known no true economy. It seems to me one of the great evidences of the great wisdom of God that the motives and acts of man are sooner or later engraved indelibly on his face—a picture that even little children may see and interpret.

* * *

BOTANY is the study of all that gives us food, life and strength; that supports all life of every kind. It is a part of the study of God himself. Botany is God's first and choicest work. We almost see God when we look at nature. We adore Him as we inhale the odor of the flowers, as we rest in the shade of trees or vines, as we bask in the sunshine. Why is this world lovely? How would you like it if there were no trees or verdure?

A WORD ABOUT HOME.

JUST now in thinking of little things which go towards making a home, I cannot help feeling how useless and worthless they are if love does not cast her light over all. What is house, furniture, luxury, if there be not love? They cannot, without it, make home—that refuge for the weary heart, for

> "Home's not merely roof and room,
> It needs something to endear it.
> Home is where the heart can bloom;
> Where there's some kind lip to cheer it!
> What is the home with none to meet?
> None to welcome—none to greet us?
> Home is sweet—and only sweet—
> When there's one we love to greet us."

Mother, if you've been cross when the boys went away this morning, smile on them when they come home to-night. Or, if you refused your husband his good-bye kiss, give him two to-night to make up for it. Do you ever stop to think, when giving way to temper, that, perhaps, this may be your loved one's last day on earth? How do we know? How can we tell? Our fathers, brothers, sisters leave us full of life and hope, but they may never return. I do not wish people to go about with a constant gloom on their faces, but would it not be better if we were to keep a watch on our tongues? Let the bitter things be unsaid.

* * *

SOME years ago, when I first left home, I felt very lonely and homesick. I pined for the woods and fields, so one day started out for a walk, alone, going towards the woods which lay beyond the city where I was then staying. To get to these woods I had to cross a river, and as I walked towards it I passed many factories which were built on its banks. While walking along I stopped to pick up a pin. (For at home we used to repeat the old lines: "See a pin and let it lay; you'll have bad luck all the day"). As I did so, a man who had been walking behind, passed me. Scarcely had he done so—before I could rise from my stooping posture—when a wagon-load of bales of cotton fell upon him. I heard a groan and a cry; that was all. I felt utterly paralyzed and sank on a step close by. The men from one of the mills ran out, and as soon as possible, lifted the bales from off him. The sight which met my eyes never left me for months. The man was flattened out as if he had been run between two rollers. They tried to restore him but he was dead. One step more and that would have been my fate! I was then a girl full of buoyant spirits, had never seen death, was as quick with my tongue as many girls are, but from that time to this I have realized how near the portal we may be—one step, perhaps. If it should be one of our number who is called, let us try not to have anything to regret. Let us make the word "home" mean something to those we love?

DORA HARVEY VROOMAN.

Boys and girls when you are misty as to whether you should or should not do a thing—ask yourselves: "What would mother say?" In most cases, if not in all, the answer will prove a trusty guide through life.

BREAD-MAKING MADE EASY.

IN the culinary department, this subject is deservedly paramount. Good bread overshadows numerous deficiencies in minor details of the repast, while the presence of no delicacy, however tempting, can compensate for its absence; but, like rich trimming on a shoddy garment, the contrast only attracts increased attention to the spurious foundation the dainty is intended to garnish.

Nearly every neighborhood contains at least one woman who excels in the art. Her bread is the delight, almost the envy of her sisters—at least until they witness the laborious process by which it is obtained. This extremely particular task is never trusted to the servant: no, not even to her own daughters, no matter how skillful they may be with cake and pastry. Even if their young shoulders were strong enough to endure the hard work involved, they would be sure to be forgetful, and a very few minutes of neglect would ruin the whole. The dough is worked and raised and re-worked several times, and the forenoon passes slowly away, ere, with weary hands and aching head, the mother removes the snowy loaves from the oven. Many a young house-wife has labored and sweated to obtain equal results, yet in vain; and almost wished herself a native of the South Sea Islands where bread grows on trees, and is always palatable.

The effect of sour, heavy bread upon the health and consequently the happiness of its consumers, has been too often discussed to need re-discussion here. It is simply the prevention of mistakes of which I wish to speak. While the painstaking woman already referred to, will produce a superior article, most of the hard labor she deems so necessary is positively useless. The main requisites are good flour, good hops and good potatoes. With these essentials, and careful attention to the directions which follow, I believe the most inexperienced will be satisfied with the result, and never again be willing to depend on baker's bread.

First, make your own yeast, and if you have access to a garden plot, raise your own hops rather than risk buying those which have already lost half of their original strength. To make the yeast is a very simple matter: Steep a handful of hops in sufficient water to cover nicely. Meantime, grate six medium-sized potatoes, over which pour two or three quarts of boiling water. The mess should thicken like starch. Add the water strained from the hops, a tea-cupful of white sugar and a table-spoonful of salt. When nearly cold add a-quarter of a cup of old yeast; or, better, to avoid using so much old yeast, when first made take out half a tea-cupful. This will soon cool. To it add one tea-spoonful of old yeast, and put in a warm place to rise. By the time it is light, the bulk of the yeast will be cool, to which it may be added. This should be allowed to rise to three times its original bulk, about three times, stirring down *briskly* each time. Then cover closely and put in a cool place for use. Yeast so made seldom moulds, but in the warmer months it should be renewed once in three or four weeks.

From the yeast-making to the baking, a milk-warm temperature is most favorable to the process; a lower temperature retards, while freezing or scalding destroys the leavening properties of the yeast. Never put it in a place too warm to bear the hand with ease, till it is ready for baking.

For two loaves take one quart of warm water, half a cup of yeast, from one to three cups of mashed potato, (whatever is left from dinner) one table-spoonful of lard or butter and two table-spoonfuls of sugar. Mix stiff and knead for 10 minutes. Cover closely and set in a warm place to rise. I usually set the sponge shortly after tea. (Of course, this cannot be done in winter unless the fire is kept "alive" during the night.) In the morning, before commencing breakfast, the dough is worked for five minutes, then made into loaves. By the time breakfast is over, these are usually ready to bake. Thus that terrible bug-bear, bread baking is accomplished almost before the breakfast dishes are washed. No extra fire is needed in the forenoon to swelter in—only a slight prolongation of the one that prepared the morning meal.

The bread should bake from 15 to 25 minutes in a moderate oven. Much bread is ruined by over-baking. The fresh, sweet taste is literally cooked out, leaving a dry, insipid mass. A little practice will enable one to tell by tapping lightly on the loaf, when to remove it. When baked, it should be taken from the tin at once, and placed between two folds of cloth to steam. Bread made in this way is light, soft, fine-grained and absolutely free from the hop taste to which many object. Just try the experiment with some friend who thinks he can eat only "salt-rising" bread, and see if he does not relish this; while the devotee to the "hoppiest" of hop-yeast bread will be equally pleased.

If hot bread rolls are desired for tea, take sufficient dough for one loaf, add a little more lard, and knead till it is thoroughly mixed in. When the sponge is light, roll thin and cut with a biscuit-cutter. Dip half of each piece in melted butter, fold over on the other half and place in the baking-pan. When light, set in a cool place till time to bake. For rusk, take the same amount of dough as for rolls. Add one tea-cupful of sugar, one table-spoonful of lard or butter, and one egg, well beaten. Knead thoroughly and let the dough rise again, then work it into biscuit. When they are light, bake in a moderate oven. As soon as they are done, cover the top with a dressing of sweet cream and sugar, equal parts. Butter may be substituted for the cream. I am sure that no one who tries this method will desire to return to the old method of kneading and re-kneading till it fairly makes one's back ache to think of it; neither will she be worried by the anticipation nor mortified by the reality of poor bread.

RUTH RAYMOND.

A PARTIAL CONVERT.

I WAS presented a few days ago with a handle dish-cloth which I find very convenient, especially in washing around the handles of tea-cups, tumblers, narrow-necked pitchers and vases. I don't know that I could quite get used to it in washing all kinds of dishes; for it is hard to change for one who, for over 50 years, has washed in the old way, but there are many persons who cannot put their hands into any greasy water without suffering, the hands smarting and burning; for such this kind of dish-cloth would be invaluable. Mine has for a handle a round stick an inch in diameter and a foot long. When the handle is ready, cut enough coarse twine into pieces eight inches long to make a swab large enough to be wrung easily with one hand when doubled. Cut a groove about one inch from one end of the handle. Double the twine and tie it on evenly around the stick. Be sure it is bound on solidly; and it is then ready for use. We use one to clean our lamp chimneys, only we tie on sponge instead of twine, so that there will be no lint on the chimney.

When You Know

That scores of people have been cured of Boils, Carbuncles, and Scrofulous Sores by the use of

Ayer's Sarsaparilla

why not try it yourself? As a blood-purifier, this medicine has no equal. Listen to good advice: Take Ayer's Sarsaparilla, and no other.

"I had numbers of carbuncles on my neck and back, with swellings in my armpits and was tormented with pain almost beyond endurance. All means of relief to which I resorted failed until I began to use Ayer's Sarsaparilla. One bottle of this remedy restored me to health."—S. Carter, Nashville, Tennessee.

Ayer's Sarsaparilla,

Prepared by Dr. J. C. Ayer & Co., Lowell, Mass.

Price $1: six, $5. Worth $5 a bottle.

THE GREAT ENGLISH REMEDY.
Beecham's Pills
For Bilious and Nervous Disorders.
"Worth a Guinea a Box"—but sold
for 25 cents,
BY ALL DRUGGISTS.

GOLD MEDAL, PARIS, 1878.
W. BAKER & CO.'S
Breakfast Cocoa
Is absolutely pure and it is soluble.
No Chemicals
are used in its preparation. It has *more than three times the strength* of Cocoa mixed with Starch, Arrowroot or Sugar, and is therefore far more economical, *costing less than one cent a cup.* It is delicious, nourishing, strengthening, EASILY DIGESTED, and admirably adapted for invalids as well as persons in health.
Sold by Grocers everywhere.
W. BAKER & CO., Dorchester, Mass.

News of the Week.

HOME NEWS.

SATURDAY, August 3, 1889.

THE rejuvenating effects of Dr. Brown-Sequard's subcutaneous injections of his newly discovered "Elixir," lasted only two months, and he is now lively and young again at 72, under the effects of a second experiment. The effects passed off in the same time in the cases of several other old men who had been similarly treated. Dr. Hammond, one of the most skillful and probably the best known physician in America, has just been making similar experiments on some feeble old subjects at Washington, and reports marvelous results in the way of restoration of mental and physical strength, and buoyancy of feeling. Some doctors are in hopes of marvelously beneficial results from a discovery which is still in an empirical stage—simply in its infancy—others declare that the fuss is all poppycock, caused by the senile maunderings of an old scientist in his dotage..... Slugger Sullivan was arrested here last Wednesday by a Mississippi deputy sheriff on a requisition from Governor Lowry indorsed by Governor Hill. No useless opposition was made and at 4.30 P. M. Thursday the party started quietly for Jackson, which they will reach on Monday. In Mississippi prize fighting is a misdemeanor punishable by a fine of not over $1,000 or under $500, or by imprisonment for not over one year or under six months, or both. Most people here think the Prince of Sluggers will get off with a fine; many, however, believe he'll be punished to the full extent of the law as a warning to all other bruisers. Kilrain has hitherto escaped arrest. .....On June 11, the United States revenue cutter Rush, cruising in Behring Sea, overhauled the British sealer Black Diamond cruising in forbidden waters. The Diamond refused to heave to until the Rush's guns were run out to sink her. An investigation discovered 103 fur-seal skins. A demand for the sealer's papers was refused, and Captain Shepperd of the Rush broke open the Diamond's cabin and strong chest and secured them. The Diamond, like several other sealers in Behring Sea, would have resisted if she had not met with superior force. The Rush also stopped the Triumph, another Canadian sealer, outside of Behring Sea, but as no seal-skins could be found, she was permitted to go. A good deal of warm feeling finds expression in hot words at the "outrage" across the border, especially in British Columbia on the Pacific coast. Such intemperate heat would be foolish at any time, but is specially so in this torrid weather. If the American officer transcended his rights, due reparation will be made; if not he'll be sustained. When, in 1867, the United States bought Alaska, the Aleutian and Seal Islands, etc., from Russia for $7,200,000, all the rights Russia had previously claimed were transferred to this country. Among these was a claim to exclusive jurisdiction over about half of Behring Sea, Russia still claiming jurisdiction over the part adjoining her Asiatic possessions. England, the United States and other maritime nations refused to concede Russia's claim at an earlier day, on the ground that it could be maintained only if the Sea were inclosed or land-locked, whereas on the south it merges into the Pacific Ocean from which it is here and there separated by the long chain of the Aleutian Isles several thousands in number. England, or rather Canada, now insists that the jurisdiction of the United States cannot extend over an open sea, upwards of 1,000 miles across, but must be confined to three nautical miles from the coast of the mainland or any island. The Alaska Commercial Company leases from the United States the exclusive right of catching fur seals in Behring Sea under strict rules against the extinction of the animals, and takes over $125,000 worth of skins a year, almost entirely on the Seal Islands, in the middle of Behring Sea. Many Canadian and a few American vessels are engaged in catching seals surreptitiously, on the islands when they can, but generally out at sea as the animals are engaged in their annual migration. Most of those struck then sink and are lost, while the skins of many of those caught are worthless at that season. These "piratical" operations have in five years destroyed two-thirds of the seals and would have annihilated the business in five more. This would be a serious loss to this country which produces the animals: to England where the skins are prepared, and to the world which uses them. The United States insists on a stop being put to the reckless, cruel, wasteful and greedy slaughter, and England is hardly likely to embroil herself with this country in support of a few unscrupulous men who persist in it for purely selfish gain..... The Canadian Department of Justice has granted extradition papers in the case of Burke, the Cronin suspect, imprisoned for several weeks at Winnipeg. A mint of money has been vainly spent to prevent his extradition. As he hadn't a cent, and all his people are poor, where did it all come from?..... On Thursday, August 1, Plymouth, Mass. witnessed the dedication of a fine monument to the Pilgrims who landed at Plymouth Rock. The day was the anniversary of their departure on the May flower from Delft Harbor 269 years ago. On November 20, 1620, Cape Cod was sighted, and on December 30, Plymouth Colony was founded: while the building of the town was begun on January 2, 1621. Thursday's celebration was fairly good in spite of a heavy downpour which deluged visitors and made the streets sloughs of hub-deep mud..... A disastrous storm of wind, rain and lightning terrified and greatly damaged Chicago a week ago. The "oldest inhabitant" had never seen anything so bad. Houses were blown down, causing several persons' deaths and wounding others; trees were up-rooted, telegraph and telephone wires prostrated; cellars and low parts of the city flooded and general havoc created. Loss over $100,000. With a sewage system for a place of only 100,000 inhabitants and a flat situation, the culverts couldn't admit the deluge into the sewers nor could the latter carry it away fast enough. Hence the town was flushed with sewage from the sewers and privies, and this having made its way into the lake, floated to the Crib through which Chicago gets its water supply. Hence danger of pestilence. So many molded bricks were reduced to mud that bricks at once went up $1 per 1,000. The drainage of the Lake City has long been a puzzling problem, now it demands prompt solution..... The Montgomery Cemetery at Norristown, Pa., draws the line at negroes. The other day it refused a burial permit to a colored war veteran despite pressure from the G. A. R.; but on the same day it granted one for the interment of a pet poodle. The veteran was incased in an ugly, plain pine coffin, however; the dog in a beautiful, silver-handled black-walnut casket. One was jolted over the stones in a rude cart; the other borne smoothly in a gorgeous hearse. .....Every summer there's either a strike or lockout, or both, in the glass-workers' trade. The men get higher wages than do any other class of operatives in the country or the world, and are protected from competition by rigid rules with regard to the number of apprentices that can be employed by any firm. The work round the furnaces is hot in summer; hence the strikes to give the men holidays and the employers an opportunity to clear out surplus stock. Both having partly gained their objects, negotiations for settlement are becoming friendly, and no doubt will soon be of fraternal warmth. Sympathy for striking glass-workers is foolishly wasted.....Charles M. Reed, a level-headed millionaire of Erie, Pa., offers to pay off the city's debt, amounting to $1,100,000, if it will give him the franchise of supplying the inhabitants with water. It would be worse than folly to give the control of a necessary of life in constant use to a speculator. .. Henry George has arrived here hale and hearty after five months in Europe, spent chiefly in lecturing. He says the single-land-tax doctrine is spreading steadily across the water, especially in Great Britain. There's a split in his party here..... Is it a matter for regret that there has been a falling off of over 100,000 in the immigration for the year? Hardly. There's no lack of all kinds of labor here already. .....A syndicate has bought the natural gas rights on 80,000 acres in Indiana, and intends to lay two eight-inch pipes, 138 miles long, to Chicago. Gas is to be pumped through these for the supply of the city, for lights and fuel, the work to be finished by Nov. 1. An Indiana law prohibits any gas being run out of the State, but the lower courts have already declared the law unconstitutional, and the higher courts are expected to do the same. ... .. An English syndicate has purchased 78 grain elevators in the Northwest, and another is negotiating for those in St. Louis. Other English syndicates are trying to get hold of the largest dry goods concerns in the country, and one is negotiating for the leather factories of Newark, N. J., the largest in the country. When these syndicates or trusts are formed, they are well "watered" and the diluted stock or certificates are offered for sale to the public, the "promoters" giving the original owners a large proportion of the "water" as an inducement to sell, and retaining the rest as their own perquisite. Their contract for the various kinds of business usually is on the "option" plan—if they can "place" the stock within a certain time the purchase is completed; if not, the enterprise collapses. Many of the "promoters" have little or no money of their own in the concerns they set "afloat," so that they may make a great deal and can lose only their labor at the most, and generally they manage to get paid for that. The American Salt Syndicate or Trust has just collapsed because the public here and abroad refused to invest largely in the enterprise. Salt is a necessary of life, and is one of the most plentiful of minerals; it would be an impossibility as well as an outrage therefore to monopolize it; and, again, the outcry here against the project frightened off possible investors. "They say" it may start again later on; but——. A financial panic is inevitable in the future when the bottom falls out of many of these undertakings..... ..... A Ballet Girl Trust! Yes, a Chicago syndicate, three-fourths of whose capital has been contributed by Englishmen, has already engaged the services of 3,000 Western Amazonian beauties. Some will get full pay and work; others half pay while unemployed. The threaters first and the dear public last must foot the bill—the least evil kind of trust: one on "luxuries pure and simple."..... The axe-wielder of the Post-Office has beheaded 13,000 fourth-class postmasters since March 4, 1888, against 9,000 decapitated in the same time under the last Administration..... ...It is probable that the Dominion militia system will be extended to the Northwest next year..... One of the richest deposits of petroleum ever struck, is said to have been found, on July 13, near Crow's Nest, in the Rocky Mountains, 4,500 feet above sea level in Canada. Samples show 91 per cent. of lubricating oil, five per cent. of heavy oil, and the rest water..... St. Louis, unwilling, of course, to yield a point to Chicago, insists that it is the best place for the great International Exhibition of 1892. The Chicago papers are villifying New York and everything about it, by way of boosting the chances of the Windy City for the Snow. Cincinnati, too, is putting in a modest but firm claim, as a central point, and Boston wants a side-show display of her own for the products of New England. New York conscious—perhaps too conscious—of her paramount advantages, is calmly—perhaps too calmly—preparing to secure the prize, while Washington is husbanding her strength until she can overwhelm Congressmen with it. All agree that it ought to be the finest thing of the kind the world has ever seen; can there be really more than one opinion as to the city that is best able to make it that?..... Ex-Senator E. H. Rollins, of New Hampshire, died at eight o'clock Wednesday morning at the Appledore House, Isle of Shoals, aged 64 years.....Based on the data of its city directory, St Paul, Minn., claims 185,000 population; based on the data of its city directory, published nine days later, Minneapolis claims 230,000! Both are marvels in their growth as well as in their pretensions.. .....A movement is on foot to celebrate the 30th anniversary of the discovery of petroleum by sinking the first well, at the junction of Pine and Oil Creeks in Western Pennsylvania, by Colonel Drake in 1859. Oil was struck at a depth of 71 feet and the flow was 400 gallons a day. The total output was 2,000 barrels in 1859; 104,000 000 in 1864; 470,000,000 in 1874, and 1,148,000,000 in 1888..... Murat Halstead, of the Cincinnati Commercial-Gazette, who was so unceremoniously rejected by the Senate as Minister to Germany, and who has been abroad for the benefit of his health since May 22, has just returned in good health, to make things lively for the Republican Senators who defeated his nomination, either as a virulent colleague from Ohio in the Senate, or as a vitriolic scorcher in the press.....The Standard Oil Trust has bought out the White Lead Trust—for $60,000,000, "they say." The W. L. T. is "protected" by 40 per cent. duty on foreign competition, and there's much talk on all sides about "disciplining" this "conspiracy against the people" when Congress meets..... State Judge Manwaring at Stillwater, Minn., last Monday, decided that the anti-dressed meat law of Minnesota is unconstitutional inasmuch as it infringes on the domain of Congress, which can alone legislate on inter-State commerce..... Recent inquiries with reference to the wages of negro labor in industrial enterprise in the South shows that things there are somewhat different from what is generally believed in the North. Inquiries were sent to 300 leading Southern manufacturers, representing blast furnaces, rolling-mills, iron works, mines, lumber mills, saw mills, etc. Replies were received which represent 9,000 negro employés, of whom 2,500 are skilled. The average wages paid common negro labor is $1.10 per day, and skilled labor runs from $1.75 to $2.25 per day, though several correspondents pay colored puddlers, heaters and rollers $4 to $5 per day. There is no difference between the pay of whites and blacks for the same class of work. The manufacturers are unanimous in the opinion that for common labor in the Southern States the negro is more efficient and useful than the white. Many state that the negro is making progress in skilled work..... ..... of the many other demands on their pockets made by various other phases of the Irish cause.....Recent bye-elections for members of Parliament still indicate a steady current of public opinion in favor of the Gladstonites. The last bye-election was in Marylebone, one of the western precincts of London, and a hot-bed of Conservatism. The Tory candidate won, of course, but there was a Conservative loss of nearly 1,000 votes from the returns at the last general elections, and a corresponding Liberal gain. The story has all along been steadily the same; Home-Rulers have uniformly succeeded to Home-Rulers; Home-Rulers have nearly always succeeded Conservatives where the former Conservative majority was small, and where it was too large to be entirely overcome, it has in nearly every case been greatly cut down. If a general election were held at present, there's little doubt that the Gladstonites would secure a majority; but the consciousness of this fact will induce the Conservatives and Liberal-Unionists to keep in power as long as they can by refusing to dissolve Parliament. This body must be dissolved once every seven years; but the term of the present House of Commons has over three years yet to run unless the Ministry should voluntarily dissolve it after a defeat on some vital piece of legislation, or if they thought that, in consequence of some turn of good luck, they could "carry the country."..... The other day a dreadful earthquake caused great loss of life and property in the western part of Kiou Siou, the southernmost and smallest of the three large islands which, with about 4,000 smaller ones, comprise the Empire of Japan. Its area is 16 836 square miles and its population about 7,500,000. In the last 1,500 years 157 earthquakes have been recorded in Japan—an average of one in 10 years. Within the last 100 years they have been increasing in frequency. The most destructive was that of 1854 when 200,000 lives were lost in Yeddo (now called Tokio) and the surrounding country..... .. .. The Yellow River in Central China, with a course of 2,000 miles and a drainage basin of 200,000, is again on the rampage in the province of Shantung through which it passes before entering the Yellow Sea. Broad, shallow and tortuous, it frequently overflows vast areas of the country along its lower course, causing enormous losses of life and property, and all efforts by native engineers to confine it within its banks have proved vain. Foreign engineering aid is considered imperative. Ten large government sections are now 12 feet under water.....

Waited Two Months.

ATLANTA, Ga., December 21, 1886.

"To make up our minds whether or no to send for a treatment of Compound Oxygen for a dear wife, who was lying at the point of death. Oh, no, there was no time to wait; it was ordered by telegraph, and a marvelous cure was effected. But would such a cure last? Let us see:

"*Your Compound Oxygen Treatment has restored my wife to perfect health.* When I telegraphed for the Treatment we were very solicitous regarding the state of her health. She had been a very sick woman for eighteen months previous to the date your Oxygen Treatment arrived. Within 90 days' time she has been restored to perfect health. *We have waited two months in order to see if the improvement was permanent before writing the facts to you, and we say with all candor that to Compound Oxygen is the credit due.*

I omitted to say that we *cured our little ten-year-old boy of catarrh by the same Treatment.*" WALTER T. FORBES.

We publish a brochure of 200 pages, regarding the effect of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia; all chronic and nervous disorders. It will be sent, free of charge, to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa., or 120 Sutter Street, San Francisco, Cal.—*Adv.*

FOREIGN NEWS.

SATURDAY, August 3, 1889.

SATURDAY last, the Princess Louise, aged 22, eldest daughter of the Prince of Wales, was married at Buckingham Palace, London, to the Earl of Fife, aged 40, who thereupon was created Duke of Fife, by his grandmother-in-law, Queen Victoria. The wedding presents were worth over $750,000..... The debate in Parliament on the annuity grant to the Princess and that to her eldest brother, Prince Victor on his approaching marriage, ended, as was expected, in an overwhelming majority in favor of the grant, or rather an increase of $200,000 a year to the civil list of their father, the Prince of Wales, who will hereafter provide for his own children. After all, the national income of the Queen of England and Empress of India and her family, is much smaller than that of any other royal or imperial family, considering the wealth, power, area, and population of the different governments.....The other day vast crowds turned out at Edinburg to welcome Parnell who received the freedom of the city, a mark of the highest appreciation of honorable service in military or civil life. Of course there was a strong protest from a large minority of disgruntled citizens, but all the world over, while the acts of the majority, however slim, bear lasting fruit, those of the minority, however stout, are generally barren ..... Now that the Parnellite investigation is virtually over, it is found that the Parnellite Indemnity Fund, contributed by friends of the Parnellite cause all over the world to defray the expenses of the defendants, exceeds $200,000, while the actual costs were only about $100,000. Good judgment and great economy is herein shown on part of the beneficiaries, and wonderful generosity on the part of the contributors, especially in view

AGRICULTURAL NEWS.

SATURDAY, August 3, 1889

THE weather for July, especially the closing days of the month, has been decidedly damp in most parts of the country, while some sections have been visited by destructive tornadoes and floods. Near Plainfield, N. J., July 30, the mountain streams back of the city, burst several dams and swept down upon the residence portion of the town, destroying many fine buildings, and flooding the lowlands below. At Orange, N. J., the same causes produced similar results, much damage to crops on lowlands resulting in each case. The same morning a tornado struck a small hamlet four miles back from Highland, N. Y., and leveled houses and barns, orchards and vineyards to the ground, and people and stock were injured. One vineyard of 10 acres was swept clean of everything, and every tree in the orchard on the same farm was uprooted. Kingston, N. Y., reports the vast grape crop almost ruined. Pittsburg, Mass. reports a flood which did much damage to crops. Severe thunder storms with much damage to crops are reported from different parts of Arkansas. On the Delaware Peninsula the peach crop has been greatly injured. One dispatch tells of farmers wading in water up to their knees to pick peaches. Heavy losses of peaches and grapes are also reported from Michigan, and other localities. Usually such reports are far in excess of the actual damage, and we trust this is the case now.... ....A Sweet Potato Trust is reported from Baltimore.....Large quantities of apricots, prunes and peaches are being dried in California..... Dairy Commissioner Thom of Wisconsin, has issued, for general circulation, a small pamphlet containing the laws which it is his duty to enforce.....It is reported that, owing to storms and low prices, 1,000,000 quarts of cultivated blackberries were left to rot on the vines along the Delaware and Maryland boundary line..... ..The American Strawboard Company has purchased the paper mills, at Lima, Ohio.....An Indiana farmer was kicked by a steer and killed. The steers should be de-(or dis-)legged.....The fertilizer factory of E Raun & Sons, Indianapolis, Ind., was destroyed by fire. Loss, $50,000 on stock. .....Lady Baker, an Iowa Holstein-Friesian cow, is reported as making in the week June 14-20th, 34 pounds six ounces of unsalted butter from 542.13 pounds of milk. To effectually silence all doubters, three affidavits are appended to this statement. The cow was milked thrice daily..... A mad dog bit several cows near Plainfield, N. J., recently, and a number of them have died of hydrophobia.....Peaches are reported so plentiful in some parts of Texas that the market is glutted .....Over 6,000 boxes of cheese were soaked with water in the cellar of a Chicago warehouse last Saturday night. As the water had previously scoured the dirty city streets, the condition of the cheese can be better imagined than described.....Large areas of land in Australia formerly unfit for stock-raising, have been rendered available for that purpose by means of artesian wells .....The use of straw for making an interior finish to take the place of lath and plaster is suggested.... ....Western railways have made a change in the minimum weight on car-lots of live stock, that is favorable to the farmer and shipper. Under the old order cars 30 feet long, and underloaded with cattle, were charged at not less than 20,000 pounds; now the minimum is 19,000 pounds for 31 feet and under..... The Statistician of the Department of Agriculture estimates the total value of oxen and other cattle—as contrasted with dairy stock—in the United States to be $14,513,708 less than the value of the same stock at the time of closing his report last year. Dairy stock has maintained its value.....The Department of Agriculture has selected seven varieties of winter wheats for general distribution. Three are new, that is, have had only a local reputation, while three are well known in some States, and unknown in others where they will be distributed exclusively. Five varieties have also been ordered from France, three being of southern origin, which will be distributed to the Southern experiment stations. The other two are wheat crosses by Vilmorin, and will be distributed to the Northern experiment stations.....The town board of Corydon, Indiana, has passed an ordinance forbiddding horses, cattle or hogs to run at large under a penalty of $10 for each offense..... Incendiaries have fired a number of farm barns in different parts of Indiana... ..... California fruits are sold at auction in Chicago, Boston, Kansas City, and other cities as well as New York.....Delaware farmers are reported to be sowing large quantities of buckwheat..Three-year-old colts now have a better record than four-year-olds, the best record in the latter class being Manzanita's 2.16, against Axtell's 2.15: The fastest five year-old record is 2:10¼ by Jay-Eye-See.... The Nelson County Agricultural Association will hold their 24th exhibition at their grounds near Bardstown, Ky. September 3-6, A. R. Carothers, Secretary.... ..... A Sweet Potato Trust has been organized in Baltimore.....Last week there were shipped from this port by foreign steamers 3,810 head of live cattle, 8,480 quarters of beef, and 47 live sheep. Shipments from other ports for the same time were, Boston, 2,716 live cattle and 5,591 quarters of beef; Philadelhia, 1,588 quarters of beef; Baltimore, 226 live cattle; Montreal, 5,625 live cattle and 5,849 live sheep. Total receipts in this city last week were 12,972 beeves, 134 cows, 7,170 calves, 44,570 sheep, and 29,574 swine..... The Philadelphia Board of Health has been prosecuting milk-men for adulterating milk. One sample was 18 per cent. water....At Saratoga on Wednesday, Los Angeles beat Hanover by a neck in a 1¼ mile dash: time 2:13... At Cleveland, August 1, Axtell trotted a mile in 2:14¾ and Guy in 2:10¾... ... ...A horse with all the symptoms of hydrophobia ran through the streets of Chicago, and bit two men and eight horses before he was shot..... ....A farmer near Ithaca, N. Y. attempted to rescue two colts which had been attacked by bees, and was so badly stung that his life is despaired of. One horse is dead, and the other is not expected to live ....State Dairy Commissioner Brown, of New York, is distributing 10,000 copies of the new law for the prevention of the adulteration of vinegar. .....Health Inspectors confiscated an entire cargo of 8,000 bunches of decayed bananas weighing 163 tons..... The hay crop of New England is said to be the largest ever cut ..... A farm in Cambridgeshire, England, valued a few years ago at $65,000, sold recently for $19,250..... Prof. C. V. Riley has received from the French Minister of Agriculture the insignia of a Knight of the Legion of Honor, accompanied by complimentary letters from the Minister and the Director of Agriculture..... Preparations for the survey for the Government Irrigation work have been begun in New Mexico, Colorado, Nevada and Idaho... ....In East and Middle Kent and Sussex, England, the largest hop crop for 70 years is expected.....East India wool is now being imported at New York.....Ocean freight rates on cattle have nearly doubled within a year.... ..... The National Wool-Growers Association met at Columbus, O., July 29. The only business reported was the passage of a long string of resolutions .....A special wool train of 20 cars was run from Los Angeles to Boston, going through on passenger time..... A California breeder lost a valuable stallion as the result of treatment by a quack veterinarian. There is a moral to this.....

FIVE HARVEST EXCURSIONS.

THE Burlington Route, C., B. & Q. R. R., will sell, on Tuesday, August 6th and 20th, September 10th and 24th, and October 8th, Harvest Excursion Tickets at *Half Rates* to points in the Farming Regions of the West, Southwest and Northwest. Limit 30 days. For circular giving details concerning Tickets, rates, time of trains, etc., and for descriptive land folder, call on your ticket agent, or address P. S. EUSTIS, Gen'l Pass. and Ticket Agent, Chicago, Ill.—*Adv.*

Crops & Markets.

SATURDAY, August 3, 1889.

REPORTS from the West and Northwest say that winter wheat thrashing is progressing very slowly on account of the wet weather; but that where it has been done, the yield has been better than was expected. Much depends upon the weather for the next few days. It is impossible to make any estimate of the spring wheat, as harvest has just begun. The crop is very uneven.

The wheat market is dull. Cable advices say that the Hungarian crop is short, but Hungary will carry over considerable old wheat; that Russia has an abundance of old wheat, and that France will need to import but little. The Australian crop is short. The visible supply east of the Rocky Mountains is 12,134,511 bushels against 22,190,501 bushels one year ago. Receipts at all points are smaller than at the corresponding time last year, and 1887. Taking everything into account, and also the fact that stocks of flour are well cleaned up, it is difficult to see why the price of wheat should not be well maintained, it not materially advanced.

Oats are the heaviest crop known in years. The weather has generally been very unfavorable for harvesting, and the crop has been injured to quite an extent. This in connection with the poor outlook for corn will tend to strengthen prices, although the stocks on hand are reported to be more than double those on hand one year ago.

Corn prospects are poor, and are growing worse in many places. In some localities there has been no regular corn weather since the crop was planted, and wet weather has hindered or prevented cultivation so the crop is likely to fall below an average. Stocks reported on hand are less than one-half what they were at this time last year. Good corn will be good property to have for some time to come.

Barley is uncertain, and it is difficult to say what the prospect is. The only certain thing about it is the very rainy weather all through harvest, which has damaged the crop considerably.

Rye has not been an extra crop, and the tendency of prices is upward both for grain and straw.

Potatoes are rotting badly in some localities, but it is impossible to tell whether the crop will be materially injured. At present, prices are somewhat higher here, because the weather has been unfavorable for digging, and the supply has been considerably reduced. Prices will *probably* be good later in the season.

The market is well supplied with vegetables of all kinds, but prices are unsettled, and the prospect uncertain

Large quantities of fresh fruits are arriving from California, but there is quite a falling off in receipts from Georgia and other Southern States. It has been terrible weather to handle fruits, as it has been almost impossible to gather them. They also decay very rapidly in the hot and humid atmosphere. A ship arrived during the week with 18,773 cases of California canned fruit.

The first bale of new foreign hops reached this city during the week, more than a week in advance of the earliest previous receipts.

Reports from the rice-growing States, promise a heavy yield of very fine quality, unless something intervenes between now and harvest. The prospect was never better at this time.

The butter market is overstocked with everything but the best grades. Good butter is in good demand. It doesn't have to look around and coax buyers. They are looking for it.

Prominent men in the fruit trade representing various sections of the country met in this city, August 1, and organized "The Florida Orange Growers' and Dealers' Protective Association." Its object is to improve the existing methods of picking, packing, shipping and marketing the fruit. The association proposes to establish an office in Jacksonville from which full telegraphic reports of the condition of the market shall be sent daily to every shipping point in Florida, together with any other information of value to growers. It will also endeavor to secure lower freight rates, and facilities for better and more rapid transportation. The Pennsylvania road agrees to run a train from Jacksonville to New York in 72 hours. The prime mover in this new departure is Mr. E. L. Goodsell, a well-known dealer, who favors the auction system of disposing of the crop. The Committee on Organization embraces representatives from New York, Boston, Buffalo, Cleveland, Cincinnati, Chicago, Philadelphia, Baltimore and Pittsburg.

Educational.

EDUCATING FARMERS' DAUGHTERS.

I HAVE long been an admirer of the dear RURAL, content to glean, in silence, the words of truth and wisdom always to be found in its pages; but when, in one of the last numbers, I read Laura Reinhart's article on "Necessity of Educating Farmers' Daughters," I could maintain my silence no longer: for I felt impelled to tell the writer how her kind efforts in behalf of us farmers' daughters are appreciated by at least one of the number.

So accurately has she defined our position, and so thoroughly does she understand our feelings on the subject that she has placed the matter before us more clearly than we ourselves would probably be able to state it. She has struck the very key-note of our dissatisfaction. It is not that we object to living on the farms where we were born and reared and where some of us are perhaps destined to end our days; for a life can be just as noble, just as pure and exalted when passed on a farm as elsewhere. But we do protest, vigorously, against the cruel injustice, the narrow-minded prejudice that precludes us from enjoying the same educational advantages so freely bestowed upon our no more deserving town sisters, and which they regard as their rights, and not as a privilege as do we Observation and experience, both, fail to teach us that city-bred girls have any greater capacity for learning, or any more pressing need of an education than the country girl, and yet how will the education of the average country girl compare with that of the average town girl?

The latter is our superior not only in education but in society knowledge as well. What is there in the life one leads on the farm that should tend to lessen the desire for culture and refinement? Rather would it seem that the environments of a country life are especially conducive to the unrestricted development, mentally and physically, of all that is good and pure. Does the farmer imagine that because his daughter is a farmer's girl, her appreciation and innate love of the good and beautiful are not as great as those of people whose daily lives are passed among their influences, and whose advantages are superior to hers? Laura Reinhart is right when she says it is not a lack of means that causes farmers to neglect the education of their daughters. I know of more than one farmer whose sons are sent away to attend some good college or university, and yet the father does not even dream that his daughters would appreciate the same advantages, and that they are equally entitled to them. And when the son has completed his college course, he elects his own occupation in life, learning the principles of self-reliance as he progresses; while his sister who, if she had the same time and attention bestowed on her education, would be just as intelligent, just as competent, must content herself with the meagre amount of knowledge to be obtained at the public school, and when too old to attend longer as a scholar, there is nothing left for her but to settle down on the farm, where she performs the labors of the household, in payment for which she receives her board and clothes, without a dollar she could call her own or feel free to spend as she pleases. Do fathers who raise their daughters in this way expect them to learn the lessons of self-reliance and discretion in money matters? Remember this is not a suppositious example, but a case of which I have positive knowledge, and it is only one of the many of which we know nothing.

What truth is there in the plea of farmers that a bit of book-learning and a glimpse of the refinement and culture that are possible to all, only serve to make their daughters still more dissatisfied with the farm? If a girl has a natural inclination for farm life, neither a finished education nor a knowledge of music, painting or the other fine arts is likely to detract from her enjoyment of the country; but, on the contrary, both will increase her pleasure to such a degree that the attractions binding her to the farm will be strengthened, and being able to secure all the advantages that the city, as well as country, has to offer, she will have no desire to change a country home for one that can give her nothing she does not already possess.

On the other hand, if a girl displays no taste for the occupations of rural life, and does evince a decided preference for some other pursuit, why not educate her for the vocation of her choice? Farmers, do not force your daughters, against their inclination, to live a life that is utterly distasteful to them, and one that is wholly at variance with their every idea of happiness; for few women are satisfied to live an empty life, and that is what it would be to them if their heart be not in it. A FARMER'S DAUGHTER.

Various.

HUDSON RIVER VALLEY NOTES.

THE tablelands, if such they may be called, which lie between the Catskill and Helderburg Mountains and the Hudson River, are peculiarly well adapted for successful agriculture. The soil is a heavy clay, composed chiefly of decomposed slate; it is hard to work but very strong and fertile. The only fertilizer which is used to any great extent is ordinary land plaster. The surface is level enough to permit the use of mowing and harvesting machines. The roads are easily made and kept in fine condition. The bulk of the produce is shipped by barge direct to the "best market in the world"—New York City. Land sells for a high price relatively, but there is little or no demand for it and the tendency of prices is downward. Hay is the chief "money" crop, but it is not nearly as profitable as it used to be owing to the fact that New York City now draws its hay supply from a much larger territory than it formerly did. This has been made possible by the Dederick and other hay presses which compress it in such small bales as materially to reduce the cost of freights and permit the hay dealers to obtain a supply from distant points when the price is high enough to warrant it. This makes the price of the product more uniform, but prevents large profits or rather high prices when the crop is short in any particular locality. This year, however, promises to be an extraordinarily good one for the farmers of the valley; the hay crop is enormous and even if the prices rule low, the crop will net a large amount of money. After all, the majority of truck drivers and livery-stable men prefer "North River" hay, especially the clear Timothy. For some reason, probably the heavy soil upon which it is raised, it seems to go farther than the lighter grades of hay from other localities. The hay is sold in all sorts of ways. If the farmer needs the money he can sell his hay as soon as it is cut, to be baled and delivered during the fall, or he can get the dealers to advance money upon the crop, to be deducted from the returns when they are received. The wealthier farmers usually bale their hay at their leisure and watch the quotations in the R. N.-Y., and when they think the market is likely to be at its best, they ship their hay and take whatever the dealer may return to them. The owners of the barge lines are usually dealers in hay and other farm produce, and are, as a rule, very wealthy. Why shouldn't they be? They get both freight and commission on all the hay and other produce they handle and in many cases make a good round margin of profit besides.

All the latest machines for cutting and handling hay and grain are used in the valley. The platforms at the freight depots are covered with new implements and machines, and the implement dealers are jubilant. "The biggest trade we have had in years," is what they all say.

Corn, usually a poor and comparatively insignificant crop, is even poorer than usual this year. The wet weather caused it to come up late and very unevenly. The result will be a small crop. It is, however, a matter of little consequence as it is usually cheaper to buy corn than it is to raise it. A large acreage of oats will be harvested in good condition. Wheat and rye are not raised to any great extent.

The apple crop is light. Many of the trees have been seriously injured by the coddling moth. One peculiarity of the valley is the large barns and barracks for hay. These outbuildings are not placed regularly about the houses, but are located at the most convenient spots on the farms. "Hill-side" barns are the rule. They save an immense amount of labor. Why are so many of the barns left unpainted? At the present price of metallic and other forms of mineral paint, there is no excuse for leaving out-buildings unpainted. Even the immense ice-houses along the river bank are thoroughly painted and there is no reason why so many of the barns and out-buildings should be left in such a dingy, tumble-down condition. RAMBLER.

Literary.

MAGAZINE REVIEWS.

THE August magazines might nearly all be aptly termed vacation numbers, dealing as they do with excursions by river, sea and land, scenes at the sea-shore, and among the mountains and plains. North and south, at home and abroad, for simple recreation, or in search of knowledge, have these tourists traveled.

IN HARPER'S MAGAZINE, James Lane Allen pictures "County Court Day in Kentucky." From being a meeting for the dispensing of justice, it gradually changed into a gathering for the exhibition of stock, for the hiring out or sale of slaves, for the settling of disputes by fistic encounters, for the purchase of all kinds of plantation supplies, and, not only last, but first, and all the time, drinking Bourbon whisky. Here were found the venders of all sorts of Yankee notions, the quack doctor, the politician, and all sorts and conditions of rural folk. The day is still observed, but as a holiday, and more from force of long-continued habit than aught else. "Fifty Years of Photography" by J. Wells Champney, is illustrated with a portrait of Daguerre, and gives a history of his early struggles and final victory. It traces the evolution of photography from the earliest processes, and gives many of its modern uses. It is largely used in the illustration of newspapers and other periodicals, and has tended to cheapen as well as to improve such work. In science, its uses are almost innumerable, especially in the study of astronomy; stars invisible to the eye have been photographed, and, during the present year, the aurora borealis has been photographed. Instantaneous photography has enabled us to get pictures of the race-horse at full speed, of the birds on the wing, and a cannon ball in its rapid flight, as well as to take the baby's picture with any of its varying expressions. By means of the Kodak any one with ability enough to "press the button" can take pictures of persons or objects to suit his fancy. "The Kremlin and Russian Art" is a richly illustrated article by Theodore Child, descriptive of the richness and splendor of the palaces, churches and other wonderful buildings of that mighty empire. "The Fan," by Louisa Parr, gives a history of this indispensable article from the earliest times. It is a very breezy subject for summer reading. Other articles are "A Gentle Ghost," "Mexican Lustred Pottery," "Experiences of an Amateur Photographer," "The Religious Movement in Germany," etc. There are a number of excellent poems, literary notes, and the usual editorial departments. Harper & Brothers, New York.

IN SCRIBNER we have a very entertaining description of "Tarpon Fishing in Florida," by Robert Grant. The tarpon is an immense fish, ranging from 50 to over 200 pounds in weight, and from four to six feet in length, and up to five years ago had not been taken with rod and reel. Its habitat is the Western Atlantic and Gulf of Mexico, the chief fishing ground being the coast of Southwestern Florida. The headquarters of the sportsmen are at St. James City, on Pine Island, and Punta Rassa on the mainland opposite. The season generally begins in March, or when the weather begins to grow warm. From the description given of the landing of one of these mighty fish, three hours after being hooked, we should consider it a very exciting sport for those who have the patience to wait for a bite. One gentleman had fished three seasons, and had not yet caught a single tarpon. A long article by Henry Morton on "Electricity in Lighting," gives the history of the development of this means of illumination from the first demonstration of its possibility by Sir Humphrey Davy in 1808, up to its present high state of perfection. The desirability of such a means of lighting rests in the facts that, besides giving the most brilliant light produced by artificial means, it does not vitiate the air as do gas and kerosene, or give off any heat, or is it affected by currents of air. There are over 5,000 lamps now in operation in New York City alone, and this number is rapidly increasing. Under the electric light, any city is nearly as light as day. It is believed by many that the time will soon come when stored electricity can be handled and sold in the same manner that kerosene now is, so that the isolated farmer can enjoy the benefits of this greatest of modern wonders as well as the favored city dweller. Electricity is the power of the future. This is a valuable article, giving as it does, full details in regard the different kinds of lights, manufacture of the machinery used, etc. Other articles are "Form in Lawn Tennis," "How to Feed a Railway," etc. Charles Scribner's Sons, New York.

ST. NICHOLAS has "Among the Florida Keys," by Charles Frederick Holder. This is another chapter in a summer vacation along the coral-reefs of Southern Florida. The party consists of the Professor, and several boys together with Long John, the boatman. They discover all sorts of curious corals, shells, fishes, birds, sponges and aquatic animals; catch star-fish, murrys, "Jacks," a kind of mackerel, sharks, and various other strange fish, ending the chapter by Tom fastening the grains, a kind of harpoon, in a huge shark, and being pulled overboard at the end of the line, where we shall have to leave him floundering in the blue waters of the Gulf Stream. "Midsummer Pirates" by Richard H. Davis is a very exciting account of a game called "Pirates and Smugglers" played in sailboats at a summer resort by boys from two rival houses. Joaquin Miller has a story: "Captain Duck," which tells about a Modoc Indian, and "Limber Tim," a poor orphan, who became great friends at one of the frontier forts. But the stories are not all about boys. The account of Laura Bridgman, the deaf, dumb and blind woman who died recently, is given by Joseph Jastrow. In spite of her terrible affliction, and in the face of apparently insurmountable difficulties, she secured an education, and passed a comfortable and happy life, dying at the age of 60. "Little Menan Light" also tells of the bravery of a girl 12 years old who lived with her father, the keeper of a lonely light-house on the Maine coast. "The Little Persian Princess" who traveled incognita in the shape of a cat, in search of her lost brother, is by Mary E. Wilkins. Then there are "A Mutiny on a Gold-Ship," "The Bunnie's Garden," numerous poems, and excellent illustrations. The Century Company, New York.

OUR LITTLE ONES AND THE NURSERY for August, is as usual full of delights for the tiny ones of the family. The children who were so glad it rained, so they could play in the hay-mow with the pigeons and swallows, and hunt the hens' nests and find old Pussy Gray and her kits, are represented first by "a nice piece to speak" and a picture. Then the boy who gave up his dear pet frog to make a tempting dish for his sick auntie; the little girl who sailed a boat full of paper dolls; the "Runaway Penny" which Dolly found, and which the old rooster stole from her; the pansies that turned into fairy people; the dignified cat "Sir John," who sat at the table and had a napkin around his neck when he ate; the sick birdie whose mamma couldn't get even *one* strawberry to cool his little feverish mouth, and several others are shown in picture and story. It is a real mine for mothers whose little ones clamor for stories while yet they cannot read. Russell Publishing Co., 36 Bromfield Street, Boston.

MANLY PURITY AND BEAUTY

CUTICURA REMEDIES CURE SKIN AND BLOOD DISEASES FROM PIMPLES TO SCROFULA.

NO PEN CAN DO JUSTICE TO THE ESTEEM IN which the CUTICURA REMEDIES are held by the thousands upon thousands whose lives have been made happy by the cure of agonizing, humiliating, itching, scaly and pimply diseases of the skin, scalp and blood, with loss of hair.

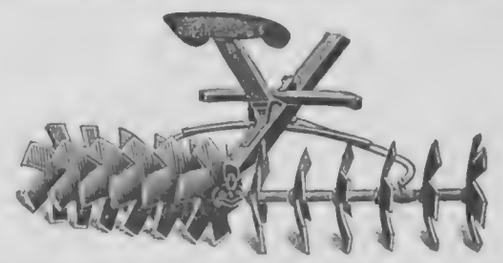
CUTICURA, the great Skin Cure, and CUTICURA SOAP, an exquisite Skin Beautifier, prepared from it, externally, and CUTICURA RESOLVENT, the new Blood Purifier, internally, are a positive cure for every form of skin and blood disease, from pimples to scrofula.

Sold everywhere. Price, CUTICURA, 50c.; SOAP, 25c. RESOLVENT, $1. Prepared by the POTTER DRUG AND CHEMICAL CO., Boston, Mass.

Send for "How to Cure Skin Diseases."

Pimples, blackheads, chapped and oily skin prevented by CUTICURA SOAP.

Rheumatism, Kidney Pains and Weakness speedily cured by CUTICURA ANTI-PAIN PLASTER, the only pain-killing plaster.



For preparing the ground for fall seeding, the Clark's Cutaway Harrow will more than pay for itself in one season. No use for the plow on stubble land. Take it and try it and you will buy it. Send for new circular.

Higganum M'f'g Corp., Sole Man'f'rs,

HIGGANUM, CONN.

IRRIGATED LANDS In Rio Pecos Valley, in Southeastern New Mexico. Choice limestone soil; abundance of pure water; a **delightful climate** all the year; almost continuous sunshine; altitude 3,500 feet; **healthiest locality** in the U. S., no consumption, no malaria. **20 acres** will yield a competency. Write for particulars, naming this paper, to **Pecos Irrigation & Investment Co., 84 Monroe St., Chicago, Ill.**

CATALOGUES, ETC., RECEIVED.

SUGAR-CANE.—Bulletin No. 23 of the Louisiana Sugar Experiment Station, Kenna, La., gives the results of last season's experiments with sugar-cane. Most of these results are of interest only to sugar makers. There are two points, however, that seem worthy of special notice. One deals with ensilaged cane. Three tons of cane were cut up in small pieces and packed away in cylindrical iron tanks seven feet high and four feet in diameter. The product was covered with paper and on this was packed dry bagasse to the depth of six or eight inches. Over this was spread a piece of canvas and on this again bagasse chips. It was then weighted, much like an ordinary silo. It was hoped that the experiment would show that cane could be successfully preserved in silos or cold storage rooms so that the season of manufacture could be greatly prolonged. The experiment failed. The cane came from the silo sour and malodorous, the sugar evidently having been converted by fermentation into alcohol and acetic acid. The other point of interest is suggested by the question: What shall we do with our chips? Three ways of using them have been suggested. They may be returned to the soil as manure, being evenly distributed by one of the improved manure distributors. They may be used as fuel. This seems like the simplest way out of the matter, but in reality it is the most difficult. The chips, even when pressed twice contain 67 per cent. of water, so that they require special fixtures and special fuels to make them burn. They can be made into paper pulp. Experiments are now being conducted by large manufacturers of paper to test the value of the chips.

KANSAS HORTICULTURE.—First Biennial Report of the State Society, Volume 17, sent by Secretary G. C. Brackett, Lawrence, Kansas. The R. N.-Y. did not expect to find the people west of the Mississippi excelling in horticultural literature, yet it is a fact that this is the best horticultural report this year. It is simple and comprehensive. Timely and practical subjects are discussed by people who seem to know what they talk about. The appendix, containing manuals on fruit, entomology, forestry and floriculture, is of special value.

OHIO ENSILAGE AND FEED CUTTERS.—Catalogue from Silver and Deming Manufacturing Company, Salem, Ohio. This catalogue contains the plans and specifications for a 100-ton silo, that many good judges consider about perfect. A full set of drawings is given and an itemized bill of materials follows. Besides this, there are 35 pages given up to a discussion on silos and ensilage that gives just the information the siloist wants to obtain. The pamphlet is neat, handy, and excellent in every respect. The "Ohio" cutters are used by many of our best farmers. Some weeks ago we gave the names of those who won prizes at the Cleveland Ensilage Convention By referring to the list our readers will see that the "Ohio" was very well represented.

PROF. GEORGE VILLE'S VIEWS.—The Commissioner of Agriculture of Georgia has done much to advertise and distribute the writings of Prof. George Ville, the great apostle of chemical farming. The July crop report of Georgia contains a supposed dialogue in which Prof. Ville argues in favor of plot experiments to determine the special needs of each field. Here are a few of his thoughts:

"The effect of an experiment field is irresistible—in face of the contrasts which it presents, practical men instinctively feel that they see a power working, formerly ill-understood, or misapplied. They understand that instead of cumbersome barnyard manure, there is a great advantage gained in the use of a few simple substances of a constant nature, which they can regulate, in both quantity and character, according to the nature of their soil, and can also increase the value of barn-yard manure by associating these well-known substances with its bulk.

If you are afraid of a little trouble, don't think of being a farmer. Agriculture is not called one of the fine arts, because it is in perpetual combat.

Good judgment is a first requisite in agriculture; and good judgment tells you that to grow full crops with economy, you must first know the natural fertility of your soil. No efforts should be spared in gaining this knowledge, which is the base on which to work; chance work ends in failure. You are fortunate when a dearly bought experience gives you the means of repairing the evil."

MUSHROOMS.—A pamphlet entitled Food Products by Thomas Taylor is reprinted from the Department of Agriculture's report for 1885. It contains descriptions and illustrations of 12 edible mushrooms of the United States, and also notes on how to select and prepare mushrooms for the table.

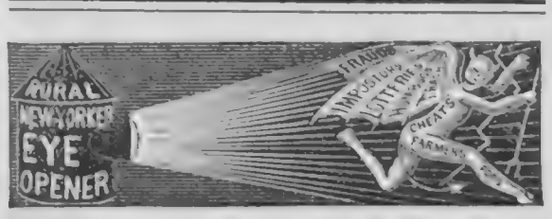
AGAINST THE SILO.—This is the only fair title that can be given a review of the two last bulletins issued by Prof. Sanborn, late Director of the Missouri Experiment Station. Everybody seems bound to praise the silo just now. It has been most persistently and effectively advertised as a very important factor in farm improvement. An argument against the silo, therefore, a question as to its economy has, just now, the merit of novelty at least. The pith of Prof. Sanborn's argument is that air-dried corn fodder is a more economical food than an equal amount of such fodder cut up and packed away in the silo. In support of this conclusion we are given a number of interesting figures dealing with the cost of cutting, hauling and handling the fodder, the amounts of water and dry matter found in it, the quantities of each sort of food eaten by cattle, the gain in pounds made by the cattle and various conclusions regarding the character of specimens of milk and butter from cows fed on dry fodder and silage.

Prof. Sanborn's experiments convince him that a given amount of dry food stored in the barn lasted longer than the same amount of food placed in the silo. While silage-fed steers made the greater growth, the ratio of growth of the dry-food-fed steers was as great or greater than the others as the silage-fed steers seemed to make a watery growth less substantial than the fodder-fed steers. Cows fed on dry fodder gave richer milk than those fed on silage, and this milk from dry fodder was the best churning milk and also contained a larger percent. of solids, while the butter made from it seemed to have superior keeping qualities. The dry food was cheaper handled and the cows seemed to keep their live-weight best on dry food. On the whole, Prof. Sanborn concludes that the trial shows that the air-drying method with dry storage in a good barn in a compact form, is decidedly the more economical method of the two, and he does not feel warranted in advising the farmers of Missouri to build silos until a radical change either in the economy of the silo or in surrounding conditions is made.

If the R. N.-Y. is able to read between the lines of this bulletin correctly, we should say that Prof. Sanborn thinks the farmers of Missouri had better build more barns before they talk about silos. And this idea is sensible. The silo is not for the sections where cattle are kept in sheds and hay is stacked out-of-doors.

We are of the opinion that Prof. S. would change his opinion on several points if the conditions surrounding him were the same as those surrounding Prof. Henry, of Wisconsin, Prof. Roberts, of New York, or others who have given the silo a very careful trial. The advice contained in these bulletins may be sound as applied to Missouri farmers, but it will hardly answer for the hundreds of dairymen in Ohio, Michigan, Wisconsin and New York, who have found money in the silo.

Here are two factors in stock keeping. 1. Warm and commodious farm buildings. 2. The silo. It makes great difference which one of these factors is first introduced. Try the silo before you reach the spirit that demands a comfortable shelter and it will doubtless prove unprofitable. Work up to the stock's comfort first and the silo will pay. There are many inaccuracies in the bulletins, and the whole experiment was marked by a series of petty blunders and mistakes on the part of the station officials, that point out the weakness of the institution. Whenever some of the wise men who framed the Hatch Bill will tell us who is responsible for the management of these stations, the R. N.-Y. will try to have the facts concerning this one brought out.



BOGUS EMPLOYMENT AGENCIES.

Among the frauds which people from the country should most carefully avoid on their arrival in New York or other large cities or towns to seek employment, are the bogus employment agencies. These are scattered in all parts of the city. All they need is money enough to advertise for a few days, a sign in front of their office dens, and inside a desk, a few chairs and a bench or two. With such an outfit, a plausible, glib-tongued, mendacious male or female scamp can swindle hundreds of needy employment hunters. Even if they have only just started in the business, they pretend that they constantly have on hand the names and addresses of a large assortment of people who are ready to afford all kinds of employment to those sent to them by the "office." Occasionally one or more of the dupes "kick" and complain to the authorities, but the matter is soon settled and hushed up and the swindle is allowed to go on. Here several such reports are made every week to the Mayor's Marshal who issues licences to employment agencies, but fraudulent places of the kind still flourish multitudinously. As a specimen, take one of five cases brought before the marshal yesterday. It is that of a notorious agency in Clinton Street, against which a number of complaints had already been made. Twelve victims appeared against it—and doubtless these did not represent a hundredth part of those who had been cheated by it in its three years' baleful existence. J. C. Valliere held a contract with it, which certified that he had paid the agents $9 for which they were to procure for him the position of collector or "any other work" in 15 days. At the expiration of that time, the poor fellow had neither money, work, nor explanation. L. Auerback had paid $8 for a like result. Agnes Simmons, a pretty 20-year-old country girl, had paid $10 for a position as sales-lady or cashier. She had called in answer to an advertisement the "agents" had put in a paper, but like several others, was told that the place had just been filled, but was informed, like a number of others, that she could get as good a place if she paid down $10. Like Miss Marie Bellevue and several others, she paid $10 out of her scanty hoard; but after wasting 15 days, not one of them all obtained a situation. George G. Eckman came to the city from a farm in Upper New York and applied to the agency for employment as a stableman. They got $10 from him; but he got nothing from them except a blackguardly tongue-lashing when he insisted on the promised situation or the return of his money. Miss Blanche Edwards could afford to pay only $1.50 as children's nurse. The rascals took her last dollar and got mad with her for insisting on receiving something in return. The Mayor's Marshal has received over 100 complaints within the last fortnight about similar rascalities committed by other employment agencies, and there's likely to be a vigorous shaking up among swindlers of that stripe soon. Even if the dens are closed, however, the owners are sure to start them again or open fresh ones of the same kind within a week or two, under the same name, or, more probably, under an *alias*.

Of course, there is a considerable number of well established and moderately honest employment agencies in the city, but these confine their business almost entirely to domestic service; and they do not advertise so extensively or glowingly as the mushroom, doubtful or absolutely swindling affairs, and are therefore far less likely to attract the patronage of strangers and greenhorns, who are apt to rely most on the most alluring promises. The fraudulent concerns are managed by the most shameless and heartless sort of rascals, male and female. They seek to make dishonest gains from the poverty and distress of the most wretched class of the community—honest people who are poor and out of work, and therefore willing, as a last chance, to risk all they can spare, and often more, in an effort to obtain some means of earning an honest if scanty livelihood. The sharpers pretend that they either have suitable openings already or can easily obtain them for any one who can raise money enough to pay for their services. On these they put whatever value they think the means or distress of the applicant will enable him to pay. While taking as much as they can get, they refuse nothing, for all they get is clear gain. Frequently they clip from the morning papers long lists of the names of people who want "help," and send applicants to these, as if they could deserve any reward for such services. A favorite trick of theirs is to send a particularly persistent applicant to various bogus addresses in different parts of the city, until finding he or she is on a wild-goose chase, the unfortunate man or woman, tired and discouraged, ceases to molest them. Occasionally, when they can secure a big fee, they send an applicant to a confederate who makes life such a burden to him that he resigns his place in a few days or a week; or if his necessities force him to hold on to the wretched place, his employer soon makes or finds some excuse for "bouncing" him. Nearly all the applicants, however, get nothing, except harsh language, in return for the fees they must pay when they make their application.

Young women who come from the country run special risk from indiscriminate application to employment agencies, some of which have regular engagements to supply "likely" help to places and persons of very questionable character. Not a month passes without the compulsory appearance of wretches who engage in this traffic before the police courts. Occasionally one is punished by imprisonment, but in four out of five cases the criminals are permitted to escape with a fine which is a mere bagatelle to them, or their cases are pigeon-holed in the District Attorney's Office and the public and the authorities soon alike lose remembrance of them. As the execrable business is a profitable one and the risks small, many are engaged in it, some of them, as exposures occasionally indicate, among the most "respectable" agencies in the city.

A common practice of the sharpers is to engage a number of farm hands, railroad operatives, miners or other classes of working men, get them to pay their fees and make deposits for transportation, and then send them to some place more or less distant from the city, where most of them are forced by necessity to work on terms much worse than those on which they made the contract. Occasionally some are sent as far away as Mexico, and these have cause for thankfulness if they can make their way back after months or years of virtual slavery and cruel hardships. Many agencies act in the same way with clerks and others of that class, especially with those who become troublesome on finding that they have been swindled.

Another favorite mode of swindling frequently practiced by these gentry is begun by advertising for a partner with a capital from $300 to $1,000 in a finely paying business! Mr. Greenenough answers and is dazzled by the specious promises of the agent, and apparent success of the undertaking. If necessary, the books are falsified and a bogus lot of customers are hired to throng the office during his visits of inspection and investigation. References are often given to confederates or friendly sharpers in different parts of the city. Nothing alluring or dishonest is left undone to tempt Mr. G. to invest his money. This once done, a change soon takes place. Sometimes the entire business with bills for office rent and several debts in the neighborhood, is left on his hands, his "partner" having vanished as soon as the money was transferred. At other times, he is either "frozen out" or the business proves of such a character that he retires in disgust. Occasionally the swindle has been so barefaced that he has recourse to the police court, but even then he rarely recovers his money, though sometimes he succeeds in having the sharper punished.

How are such dangers to be avoided? How are the trustworthy agencies to be distinguished from the untrustworthy? Probably the best plan for a stranger would be to inquire with regard to the standing of any particular agency, at one of the next offices of the Young Men's or Young Women's Christian Association before applying for help to any of them. Or application might be made to a neighboring clergyman or the police. In spite of their alluring advertisements, the best of such agencies can do little for any one who is not in search of "domestic" employment.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

VOL. XLVIII NO. 2064 NEW YORK, AUGUST 17, 1889. PRICE FIVE CENTS, $2.00 PER YEAR.

[Entered according to Act of Congress, in the Year 1889, by the Rural New-Yorker, in the Office of the Librarian of Congress, at Washington.]

Dairy Husbandry.

A VERMONT FARM HOUSE.

MANY of our readers will be greatly interested in the picture shown at Fig. 204. It is a typical Vermont homestead. There are thousands of people all over the country who spent their childhood days in just such a house. The old New England ideas of comfort and convenience are everywhere evident in this picture. The wide, sunny windows, the pleasant porch with the easy chairs for the older members of the family, the carriage-house under the family roof—who has not seen them all in good old Vermont? The front of such a house seems to light up with a sunny smile of welcome as the stranger nears it. And if we could look inside the house! It is the embodiment of solid, home-like comfort. Thousands of Vermont people have left the green hills in search of warmer climes. "I got tired of farming hillsides" was the explanation one Vermont man gave the writer 10 years ago on a western-bound train. He went to Iowa and before six months his eyes fairly ached for a sight of the hillsides he had found so tiresome.

The picture we show is drawn from a photograph of the residence of Mr. J. C. Oliver, 2d vice-president of the Vermont Dairymen's Association. We print it as a type of the pleasant old farm-houses that are scattered throughout New England. A portion of the dairy herd, composed of native stock, is shown in front, also a mare and her foal. The whole forms an accurate, home-like picture.

DAIRYING AS A BUSINESS.

J. W. NEWTON.

Why farmers don't make butter-making pay; how to do so; proper feed; handling the milk and cream; co-operative and proprietary creameries; marketing the butter; chicken meat or pork—which? "The dairyman of the future."

BUTTER is low. In the last RURAL it was quoted at from eight cents to 20 cents, 14 and 15 cents being about the average. The condition of the market is abnormal, owing to the unusually wet season which has caused feed in pastures to make an enormous growth. A drought next year would doubtless cause butter to be higher than it is at present, but there is every prospect that butter in the future will be low in price. To make a profit, it must be produced at the least possible cost. To make it at a cost of 16 cents per pound, and sell it for 14 cents is to go to ruin. It would puzzle any farmer to make a profit on eight or 10-cent butter. The less of such stuff made, the better. The trouble with farmers is that they try to do too many things. There

A VERMONT DAIRYMAN'S HOME. Drawn from a Photograph. Fig. 204.

are business men who can manage several different branches of business with success, and some farmers can do the same; but to take up such a business as dairying and carry it on successfully, might well absorb the energies of most men. In order to make butter at a profit the dairyman needs to study the following points:

1. To obtain foods that will make the most and best quality of butter at the least cost.
2. To keep cows that will make the most economical use of these foods.
3. To handle the milk so as to get all the butter in the best shape for market at the least expense.
4. To market the product at good prices.
5. To make the most economical use of the by-products.

These few points cover a great deal of ground. The better one understands them, the better dairyman will he be. Ignorance and lack of skill cause great loss. In the first place, feed is the raw material. Too many exalt the machine above the raw material. They think that if they get a few Jerseys they are relieved from further care, and that having good cows will insure good butter. Essential as good cows are to the profitable production of butter, feeding requires the greatest skill and knowledge. Shall the Eastern dairymen grow or buy their grain foods? Most of them doubtless can grow grain cheaper than they can buy it; but what to grow and how to grow it most cheaply are questions that need careful study. Grass, corn and clover must form the basis of our cattle feed. The West is learning the value of its bran; but neither the West nor South seems to place a true value upon cotton-seed meal. Still some are afraid of this, and its real value for a butter food is not satisfactorily determined. The value of silage is no longer in doubt, and silos are being built all over the dairy region. Poor pastures are a drawback, and soiling must be resorted to by the majority of Eastern farmers. The experiment stations are working on all these problems, and some are taking steps to determine the best breeds of butter cows.

When one looks back 10 years and thinks of the progress that has been made in methods of handling milk, cream and butter, he cannot help being hopeful for the future. Fifteen years ago a large proportion of the butter fats must have been left in the milk. Now practically all the butter fats are extracted. The limit of invention has not, in all likelihood been reached. The Swedish butter extractor will be a long step in advance, if it proves to be what its makers claim.

The co-operative creamery solves many of the problems connected with dairying; but proprietary creameries where a certain number of pounds of milk are estimated to make one pound of butter without any distinction between good and poor dairies, effectually discourage the breeding of butter cows. The cost of making butter in creameries averages about four cents per pound. Made at home, it probably costs five cents. When butter sells at 16 cents, one cent must be deducted for the cost of package, so that one-third of the price is used up in simply manufacturing the butter and fitting it for market.

As to marketing butter, the fewer hands it passes through between the producer and the consumer the better it is for both. The poorest months to make butter and the best months to have cows dry are July and August. Yet how few farmers act upon this well-established fact. Fall calves are best, and what a relief it would be in midsummer to be freed from milking and caring for milk.

As to by-products, a pound of chicken sells for about three times as much as a pound of hog or calf; and yet good authorities assert that it costs no more to grow a pound of chicken than a pound of pig. The experiment stations ought to settle this, and tell the farmers whether they can really make three times as much by feeding skim-milk and butter-mik to poultry as by feeding them to hogs, etc. The dairyman of the future must be a student and a wide-awake, energetic business man. He must lay aside prejudice and keep his eyes open. He must learn and use his knowledge. The better he can do these things, the more profitable will his business be.

Lamoille County, Vt.

THE statement made by a number of writers that cud-chewing gives all the exercise that cows need strikes the R. N.-Y. as being very absurd. It might as well be claimed that type-writing, piano-playing, singing, whistling or talking gives those of us who spend much of our time in such ways all the exercise needed. Exercise of the fingers or hands, of the head, mouth, jaws, of the lungs, feet or legs can never take the place of that which should develop all parts alike.

The Swineherd.

PORK POINTERS

HOW HOGS ARE HANDLED AFTER AUGUST ARRIVES.

MILK MAKES MEAT:
PEAS PREPARE PORK:
APPLES AID AWFULLY.

FROM MARYLAND.

What we all want from our hogs is profit, and the profit depends largely upon the feeding of the hog during the latter half of his life, or from the first of August to December. A field of cow-peas makes an excellent pasture about this time. The hogs on it will require very little grain, and a little later when the pods are ripening, no additional grain will be needed. To some this may seem an expensive way to feed hogs; but as a field thus treated will be improved almost as much as if it had received a dressing of manure, I think in most cases it will pay. If the cow-peas are not stocked too heavily they will last until corn is ripe, and then there is nothing to do but to throw in the corn judiciously until cold weather comes. I do not believe in penning hogs and feeding them entirely on corn or with feed. I think the prices of corn and pork are too close to allow much profit. To feed hogs or any other animal is a science, giving them full feed without allowing them to forage for a part of it, and if one is not pretty well up in this branch of science he had better let hog-raising alone. A neighbor of mine kept an account of the corn the hogs ate, and found, on slaughtering them, that the pork cost him 25 cents per pound. In contrast to this, the most profitable way to feed hogs is to make them utilize the waste. When I wheel a barrel of slops and skim-milk to my hogs, I do it with a clear financial conscience; but when I pay $16 for a ton of mill feed, I am doubtful about the result. Even if I otherwise were to make both ends meet and lap over, a spell of sickness may knock off the profit for two or three years' feeding, and sickness has laid hold of my hogs when they were surrounded by the most approved sanitary conditions. If hogs have a pasture or wood lot from which to get a part of their living, then the extra feed will pay well; but feeding them entirely on expensive grain food is a risk. As a man remarked while paying his bill for hog feed, "There is money in hogs, but getting it out—that is the problem." P. B. C.

Catonsville.

FROM MICHIGAN.

After harvest, as soon as the wheat is stacked, I turn my hogs upon the stubble fields. At this time they are in good growing condition, having run upon the clover field during the earlier part of the summer. Whatever wheat is left upon the ground is picked up and thus saved. Some persons object to this method of feeding, assigning it as a frequent cause of cholera. I have not, as yet, found this to be the case, since when wheat stands up well and is properly harvested not enough will be found in one field to injure the large number of hogs that I turn in at once. By the constant use of cholera preventives I have managed to keep my hogs in a healthy condition and thus far free from that dreaded disease.

If, by this treatment, I succeed in getting a large frame with a proper growth of muscle by September 1, I then begin to feed corn, for there is nothing superior to that for fattening purposes. The animals are liberally supplied with good well water, salt, ashes, etc. I consider this the cheapest method of making pork *i. e.* growing the hog upon clover, (for every successful farmer has plenty of that and it is as healthful feed as one can give any animal), and finally, fitting him for market by feeding corn.

I have been making some experiments in feeding hogs, but have not got far enough along as yet, to give accurately the cost of making a pound of pork. I think some pounds are made very much more cheaply than others; that there is a limit to the profitable feeding of any hog, and that when this stage is reached he should be sold, rather than kept because the price does not suit, or because we want to make him weigh more. Hogs can be made to gain very fast upon ground feed, but it is doubtful if it pays. I had one pen of nine shoats last year, that were fed upon swill made of ground corn and oats together with what whole corn they would eat. They gained over two pounds each per day, made very handsome hogs, but cost more than those raised and fattened by the former method. The scales can be as profitably used in feeding hogs as in the dairy to test the merits of the various cows of the herd.

More important than anything else is the kind of a hog that is fed. If one has the common scrub, it matters but little how, what or when he feeds, whether he weighs the feed and accounts for it or not, the one important item, profit, will be eliminated from the results. O. C. H.

Berrien County.

FROM IOWA.

I do not know what a pound of pork costs me. It is an easy matter to know at the end of the year how the accounts of the farm stand compared with their standing at the beginning; but on a farm where stock-raising and dairying are followed it is difficult to separate the proceeds for both so as to charge each kind with its proper share of expense. I have 80 acres in permanent pasture, clover predominating, which does not run out here as it does in the part of N. Y. where I was reared. The hogs are kept in one 40-acre field by a plank across the gateway between the two fields high enough to keep the animals in, but so low that the cattle can step over it. This summer I have 93 hogs and shoats, 52 head of cattle (no calves) and four horses. I have kept about the same number for several years and pasture has been abundant except in the summer of '87. What part of the pasture is chargeable to the hogs I can't tell; but I aim to make as much as possible of the pork from grass. The pigs come in April and September. (I follow winter dairying so that the fall pigs get plenty of milk.) Fifty spring pigs are getting a bushel of shelled corn a day; that will be their ration until the middle of September when they will get about all of the new corn they will eat at two feeds, which will be about five bushels (70 pounds) a day, on an average. Last year my April pigs treated in this way, when sold on January 15, weighed 330 pounds alive each; but last winter was unusually favorable for feeding hogs. The pigs that come in the fall are usually sold in August, at a little lighter weight, but it takes less corn to finish them off in the summer. As nearly as I can figure it, it takes about six bushels of corn to make 100 pounds of live pork with the grass and skim-milk thrown in. The cost of keeping the brood sows does not enter into the above calculation. Good water, shade, and a dry, warm bed are elements that enter into the production of cheap pork and it cannot be made without them. J. S.

Corning.

FROM NEW YORK.

For about 20 years I have given more attention to breeding and selling pigs than to fattening hogs. Only such as were no longer useful for breeding purposes and a few pigs each year have been fattened and slaughtered. A thoroughbred boar of the breed most popular and salable in this vicinity at the time has generally been used. Having begun with the large Chester-White, the Poland-China, Berkshire, Large Yorkshire and Small Yorkshire have been used, and the sows now in use are of the mixed blood of these breeds. The last cross with the Small Yorkshire boar has given good satisfaction, and up to the age of eight or 10 months the pigs will give as large a profit on a given amount of feed as any stock I have seen. The Berkshire and Poland-China are excellent breeds, but black pigs are not as salable here as white ones.

A sow that is to be kept for breeding may produce her first litter when 12 or 15 months old, and continue to raise two litters each year until four or five years of age, or until she fails to produce a full number or becomes a careless mother. A very old sow will kill her pigs by lying on them. With good care, suitable feed, and warm winter-pens, sows will raise an average of eight pigs to the litter or 16 each year, and these, sold when five weeks old at ordinary prices, will bring from $40 to $50; that is, an average yearly return of $45 for each breeding sow kept will be realized.

I prefer shorts and barley-meal mixed, for the grain feed, and think that $10 worth may be used with profit in a year when fed with plenty of skimmed-milk. When milk alone is fed, sows are liable to become costive and feverish, and loss of pigs will result. This condition is easily avoided by feeding the grain mixture above mentioned. Deducting the $10 in grain fed from the $45 realized from the pigs sold, $35 remain as pay for the milk and care. But with plenty of straw for bedding and as an absorbent, enough manure may be saved to pay for the labor expended. I have never made any very careful or extended experiments as to the feeding value of the milk used; but the amount received from the sales of pigs and pork has warranted the conclusion that it represents a considerable percentage of the profits of the dairy. When I began using a Cooley Creamer, 12 years ago, six pigs eight weeks old were weighed, and after being fed sweet skimmed-milk for a month, were again weighed, and their gain was sufficient to pay for the grain consumed and 25 cents for 100 pounds of the milk.

Judging by the amount fed daily to a breeding sow, I think she will use 15,000 pounds of milk in a year together with the grain feed above stated. Here again the feeding value of the milk is 20 to 25 cents per 100 pounds. It may be thought that such feeding involves a great amount of labor for the value received; but the farmer's profits are never large and a few hundred dollars received each year from the sales of pigs and pork may represent the entire net profit of a small farm and dairy.

In connection with butter-making from 25 cows, I usually raise 12 calves each year and keep six breeding sows. If the pigs are kept beyond five weeks old, each week adds to their value, and practically they are sold at all ages from four weeks to eight months. The business has proved satisfactory and profitable. With good care there is no danger of loss on a thrifty, well-fed pig less than nine months old.

A pen warm in winter and cool in summer, kept dry and clean is essential to success. A thoroughbred boar should be used. The sows should have the run of a yard in summer. They should not be bred too young, as dwarfing will result from such a course. A good breeder should be kept as long as she continues profitable. If pigs are fattened, 200 pounds weight is the limit of greatest profitableness. A good breeding sow will yield more net profit than the average cheese-dairy cow. A cow giving 7,500 pounds of milk in a year should be credited $15 for the skimmed milk where butter is made, if she is charged for the whole of the feed that she consumes. C. S. R.

Lowville.

Pork-making occupies an important position in farm economy in this section, as it is an extensive dairying region, and these two branches of the business go hand in hand, each making the other profitable.

For profitable pork, early pigs are most desirable. A cross of Chester-White and Berkshire makes as good a "porker" as any, as it is long-bodied and small-boned, matures early and fattens readily—all desirable points. Early pork is the most profitable, costing less per pound, while it brings a higher price in the market than pork made in cold weather.

The choicest of early pork may be made by feeding plenty of skim-milk with a small admixture of wheat middlings. Pea-pods, corn-husks, clover and weeds are relished and fed with profit through hot weather. The product of an acre or more of peas is an important item in cheap pork-making as well as a healthful and delicious table dish. As soon as the peas get too old for cooking begin to pull them for the pigs. Feed them in small quantities at first, increasing the amount as your own judgment and the pigs' appetite and condition demand or the weather warrants. Avoid heavy grain feeding in hot weather. This method of thrashing the bulk of the pea crop will be found pleasant and profitable; for where is the farmer who does not enjoy seeing a flock of clean, healthy pigs buried to the eyes in luscious, succulent pea-vines, munching with avidity the well-filled pods. If not fed to excess, they will eat every pea and nearly all of the vines, and for profit, just see them grow.

A "titman" pig of mine for which I couldn't get an offer of 50 cents because he was so small, although I received $3 apiece for his mates of the same litter, was fed on this diet, and without the customary finishing off on corn he dressed 268 pounds in September and sold for $7.50 per cwt. Two others of the same litter for which the buyer willingly paid me $6, were fed in the usual way (on milk dishwater and corn), until November when the best one weighed 275 pounds and netted the feeder $6.00 per cwt. Any one can figure out the difference and locate the profit.

I have no correct data from which to estimate the exact cost of fattening hogs, but I know that it is not much over the cost of keeping them as store stock. Of course, I don't refer to such stock as one sees during a day's drive through the country: animals that are turned out to pasture and do not see a pail of swill all summer long—long-nosed, gaunt and bony brutes.

The feed to give this kind of stock the fullness and beauty of contour that characterize

a well-fed hog will cost more than the beast will bring.

Well-bred, well-fed, well-cared-for stock is the only kind that is profitable, and many farmers are in need of just that kind. Well-bred hogs need well-bred farmers with intelligence enough to give them proper care; for, no matter how well-bred, even a hog will degenerate through neglect and abuse. Give the hog a place on every dairy farm, treat him well, feed intelligently and he will add largely to your profits. M. T. W.

Sandy Hill.

FROM NEW JERSEY.

The cheapest way to make pork is a subject that I am not prepared to discuss from practical experience and actual test. I have made a good deal of it and from my observations, I am satisfied that no other feed can be so cheaply raised for feeding hogs from the first of July to the middle of November as apples. I do not wish to be understood as saying that apples are the cheapest food; what I mean to say is that apples can be raised for about five cents per bushel, and at this price nothing else is so cheap, unless it be grass, with apples, and some corn. These, for the time mentioned, or for any time, make a very good feed, and one that will make pork very fast, if fed in reasonable quantities. I do not believe in what in this section is called the swill barrel; cleanliness is as good for a hog as for any other animal. We should treat our live stock in such a manner as to keep them in good health, and if we do this with our hogs we shall hear very little of cholera and the various other diseases to which swine are liable. The proper way to raise hogs is to have a good, warm pen, so that they will not suffer from the cold, and in all moderate weather in winter let them have a run outside, for the hog is by nature a cleanly animal. Breeding sows should be kept in good condition, but not too fat. All others should be kept growing, for each day that we keep stock intended for slaughter without adding to their weight causes a loss of so much food; that is, there is a loss in all stock intended for the butcher, and in all young stock, when not improving, and if they are once started the after-profit is doubtful. In case of hogs, I believe they should always be in salable condition, and that they never ought to be finished off by putting them up in a little dirty pen, and feeding all the corn they can be induced to eat for a period of one to six months. My shoats last year gained in weight almost a pound a day when they were 10 months old, weighing, when killed, about 275 pounds on an average. They were of mixed stock, including Berkshires, Chester-Whites and Jerseys, with no pure blood. I am of the opinion that the Berkshire pure and unadulterated is the best general-purpose hog. Probably a Berkshire boar and Chester-White sow will ive heavier pigs, and might be most profitable to the owner. The Berkshire gives the heaviest ham in proportion to the weight of the animal, and the lightest head; or, in other words, the flesh of the Berkshire is the most valuable, for it has most of the best meat and least of the poor, and the most Berkshires have sufficient bone and muscle not to break down. Breaking down I have found a great drawback to the Essex shoat. When I kept Essex grades a broken leg was nothing uncommon. A few years back I saw a man's hogs out in the orchard about Christmas without shelter, and the mercury was about zero. That man's farm grows poorer each year and the mortgage grows heavier. I can call to mind few cases where the owner increased his possessions while his stock were neglected or half fed. I. J. W.

Titusville.

A HOG'S HEAD.

OUR artist believes that the hog is an intelligent animal. He has maintained that he could produce an accurate picture of a hog's face, that would indicate superior intelligence. The picture shown at Fig. 205 is the result of his study. It is the head of a young Berkshire pig sent to the stockyards at Jersey City.

Horticultural.

TIMELY NOTES ON VEGETABLES.

WILLIAM FALCONER.

CORN was never finer. The land may be sandy, but water and manure will make a crop. We are now using Concord also Squantum that were sown May 6. Our earliest corn was a good deal injured by the cornworm, but this trouble stops about the 20th of July. We put in a sowing of Evergreen the third week of July, one of Concord in the fourth week, and will put in one of Cory tomorrow (August 2nd). Our falls are generally open enough to let us get the good of these sowings. These late sowings are put in the ground cleared of the early crop of corn, and in this way we get two crops of corn from the same ground.

POTATOES looked well till 10 days ago; then they began to "die off" fast. Rot has not appeared in our crop, but the quality of the tubers is not first-class, and a good many of them are discolored inside. I have planted Savoys in the furrows between the rows of early potatoes. I will lift a large patch of ripe potatoes next week and sow beets and carrots in the emptied ground. I shall also plant a part of it with red celery.

CABBAGE.—While we have any amount of peas, beans, corn and other succulent vegetables in summer, no one cares for cabbage, and in winter no one cares for common cabbage who can get Savoys, cauliflower and Brussels-sprouts, so I grow most of the desirable kinds. Of Brussels-sprouts I raise a lot from seed in May, and another in June. This is for convenience in planting more than to hit a season, for there is no fear of having them in too early, as might be the case with Savoys or cauliflowers. Savoys sown about the end of May were planted out early in July; the same with cabbage and cauliflower. But as I didn't have nearly land enough empty then or my full crop, I potted the remainder of the plants into four or five-inch pots, and plunged these in the ground in beds to await vacancies. This isn't nearly as much trouble as might appear, and it keeps the plants stocky, growing a little all the time, and when they are planted out they go right ahead growing. Cauliflowers I sow as late as the first week in July. This gives us nice stock for storing in frames for winter use.

A HOG'S HEAD. From Life. Fig. 205.

LIMA BEANS.—We picked our first lot—from out-door sowings—on July 29th.

PARSLEY.—I sowed a lot in cold frames July 17th. This is for winter use. Of course, the usual way is to lift some of the summer roots and plant them in boxes or frames for a winter crop; but these always "bolt" early in spring. That sown in July or August will not "bolt" so soon and will give good parsley till next June.

CHICORY.—I raise a quantity of what is commonly known as Whitloaf. It is large-leaved chicory. If sown in spring it will "bolt" before fall, and this renders it almost useless as a leaf crop. I sowed it July 17th. in rows two feet apart. This is soon enough and should give us strong crowns for winter work. We store the roots as we do parsnips in winter, and keep them as cool as we can; frost even doesn't hurt them. When lettuces begin to run short I put in a lot of these Whitloaf roots, tops up, in a soap-box filled with sandy soil, and put it in any warm place that is handy. Growth soon sets in, and the young leaves make a very good salad in winter. But they should be blanched, and the easiest way of doing this is to invert another empty soap-box over the one that has the roots in it, and the leaves grow up white and tender.

CARROTS.—Our earliest out-door sowing was put in on March 27th. This sowing has now all been cleared away and the ground planted with celery. Young carrots are a delicious vegetable; old carrots are fit only for stock-feeding. I have not yet sown our winter carrots, but intend to next week in ground emptied of potatoes. We often get fine carrots when sown as late as the middle of August. The carrots we are now using were sown on May 25th. It is not a question of—are the carrots old enough to use? that concerns me so much as—how young are the carrots? But, of course, the great majority of people are not so exacting about the tenderness of their vegetables.

BEETS.—Those we are now using were sown May 25th. All previous sowings have been cleared away. Our next to come in was sown June 22nd. We will next week sow a fair lot of turnip beets and about the 12th, a large sowing for winter storing. I used to raise a lot of long beets as well as turnip varieties for winter, but as the call is now entirely for turnip beets, I find it useless to raise the long varieties. When used as a vegetable, that is when simply boiled, they are served whole and anything larger than three inches in diameter is rejected; about two inches across when peeled is about right. Of course, for slicing and pickling larger beets are admissible.

LETTUCES.—On account of the superabundance of rain this summer we have had lots of lettuce all along; but they "bolt" almost as soon as they begin to heart. But after this they won't be so apt to run. We will sow a little every fortnight till the end of August when we will put in a large sowing for lettuce for use before winter sets in, and another sowing towards the middle of September for lettuces in winter.

Glen Cove, L. I.

ACTINIDIAS.

WILLIAM P. BROOKS.

A. polygama as sold by our nurserymen probably A. arguta, as illustrated in R. N.-Y. of July 27; the true Actinidia polygama bears white leaves on the ends of the shoots; valuable for its fruit.

I WISH to compliment the RURAL upon the fine illustration of Actinidia on the first page of the issue of July 27. It gives, as far as is possible in black and white, a very faithful and strikingly life-like representation of the plant from which it was drawn. The RURAL will, I feel sure, be glad to have me point out some inaccuracies in the statements which accompany the illustration. A residence of 12 years in that part of Japan in which this Actinidia grows most abundantly enables me to do this.

In the first place, as to the name: It is known to the Japanese as Kokuwa (ko-koo-wa, without much accent, and the first syllable very long; the others hurried). In the herbarium of the Sappow Agricultural College it is set down as Actinidia arguta. I am not certain, however, who is responsible for this naming. The earlier specimens collected were all identified by Dr. Asa Gray, and I think this was among them. I am not at present able to present other evidence that this is the correct name. Fortunately, however, I have considerable evidence that the Kokuwa is not Ac-

tinidia polygama. First: In the herbarium above alluded to we have another and quite different Actinidia, known to the Japanese as Matatabi (pronounced with a very slight accent on the third syllable—Mar-tar-tar-bee) to which the name Actinidia polygama is given. Second: Dr. Rein in his work on Japan, volume 1, page 148, mentions Matatabi—Actinidia polygama. Third: Prof. Kinch, now of the Cirencester (Eng.) Agricultural College, formerly in the Komaba Agricultural College, in Tokio, Japan, in an enumeration of the food plants of Japan, includes Matatabi—Actinidia polygama. (Transactions Asiatic Society of Japan; Vol XI., p. 6.)

These dry details concerning names will not, however, interest the majority of the readers of the RURAL, who may be inclined to ask: "What's in a name?"

What, if anything, concerns them is the fact that there is more than one Actinidia and that the statements published concerning each be accurate. What the editor writes concerning his own observations of the Kokuwa—the plant figured—is perfectly correct. It is only when he applies to the plant the statements taken from the Japanese book alluded to, that he falls into error. [Our plant was received from the nursery as Actinidia polygama, which we assumed to be the correct name. The quotation from the Japanese book referred to this species. The R. N.-Y. merely pointed out wherein the Actinidia of the book differed from the RURAL specimen as evidence either that ours was incorrectly named or that the book was in fault. EDS.] This I do not wonder at in view of the confusion in scientific names which I have endeavored to clear up, and in view, further, of the fact that the Japanese writer himself seems to have confused the two species.

The statement: "It often stretches across ravines or climbs about and entangles the tops of trees," can be true only of the Kokuwa—Actinidia arguta. The true Actinidia polygama is a far less rampant grower and usually climbs only over clumps of bushes. This plant it is, and not the one illustrated in the RURAL, which has "snow-white leaves" at the ends of shoots, a fruit of a "reddish yellow color" of the size of the "top joint of the little finger," and of the stems and leaves of which "cats are exceedingly fond." No wonder the RURAL cats displayed "utter indifference" when presented with Kokuwa leaves and stems. They proved themselves accurate botanists, not to be taken in by false "catnip.

The Kokuwa never has white leaves, and its fruit, which is far more abundantly produced on fertile plants than is that of the Matatabi, is larger, and, even when ripe, of a green color. The size is very variable, but on a vigorous plant the fruit will on an average be as large as the Green Gage Plum. Its skin is astringent, but the pulp, which is readily pressed out at the stem end, is delicious. The seeds are numerous and scarcely so large as those of the swamp blueberry. The fruit is extremely laxative when eaten freely. It would be unfit to eat dried, as the skin could not be separated and would soon make the tongue and throat sore. It is readily made into a most delicious jam, the skins being sifted out in the making. I brought home with me a number of cans made by my Japanese cook, of which I will send the RURAL a little sample. I believe that this plant will prove valuable here for its fruit; but it will be necessary to propagate it by cuttings from fertile vines as it is polygamo-dioecious, and from seed would produce a large number of barren plants. For ornamental purposes I have no great opinion of it except, perhaps, as the RURAL suggests, by implication at least, in parks to "form pretty arbors and wild entanglements" from "tree to tree." It is far too rampant to plant near houses or as a veranda climber, as has been often done here. It requires too much pruning and training, and is too liable to displace eave-spouts or to strangle other shrubs and trees.

For ornament the cats' favorite, the Matatabi—Actinidia polygama—is much to be preferred. It is, though vigorous and hardy, far less rampant than the Kokuwa, and the feature alluded to of developing snow-white leaves at the tips of shoots, adds much to its beauty. The flowers are almost like those of the Kokuwa, though more fragrant and less abundant; but as the plant grows, the flowers of both species are too inconspicuous and short-lived to amount to much from an ornamental stand-point. These vines are desirable, if at all, for the beauty and health of their foliage.

I send the RURAL dried leaves and also green shoots of both species. One of the dried leaves of the Actinidia polygama was a white one. The herbarium specimen from which I took it had six of these white leaves, instead of the "two or three" the Japanese author speaks of. The green shoot of this species—is from one of two or three living plants which I brought from Japan last fall. As the RURAL will see, it shows no white; this color is not, I think, produced on leading shoots, but on flowering laterals, and probably not on very young plants. Vines planted in my garden in Sappow had not developed this characteristic after three summers. The differences between the two species will be sufficiently evident from an examination and comparison of the specimens sent; and the Editor will see that his vine is like the Arguta and not the Polygama.

Massachusetts Agricultural College.

STRAWBERRY NOTES.

FROM WILLIAM FALCONER.

As soon as we had finished picking—this year about the end of June—I had the ground well cleaned and the roughest of the strawy mulch taken off; then with sharp four-pronged hoes we unfastened the soil between the rows. This was to cultivate the land, readily admit air and moisture into the soil and help exclude drought, and to form genial rooting ground for the runners. The runners now are strong, healthy, well-rooted and fit for transplanting. I am now preparing ground for a new plantation: it has just been cleaned of root crops. It has been heavily manured and subsoiled and marked off into rows two feet apart. I will set two plants close together in the hill, and the hills 18 inches asunder in the row, and any more runners these newly-set-out plants may make this season will be cut off as soon as noticed. If short of ground elsewhere, I will grow a row of small lettuces, radishes, Horn Carrots or other small crop between the strawberry rows; but if I have plenty room elsewhere, I will not crop between the rows, but, instead, keep them well cultivated so as to strengthen the plants. In December I will scatter some well rotted manure broadcast all over the strawberry patch; then some salt hay or sea thatch thinly over the plants to protect them from sun and wind in winter.

From the strawberry plants I set out each year in this way about the end of July or in August, I get a capital crop of fruit the June following, and always our largest berries.

The chief trouble of fall-planted strawberry plants is that they are set out too late to become large and well-established before winter sets in, hence they get heaved by frost a good deal and many of them killed. I am not troubled in this way, as our young plants are just as firmly established as are the old ones.

A farmer with plenty of land perhaps can afford to plant in spring, but a gardener cannot very well do this. We never could afford to keep our ground occupied for a whole year with a crop that has not borne us any fruit. I never do. Every rod of ground has to produce something every year. And if there is an unproductive crop in the ground, such as asparagus the first year or young fruit trees, we get catch-crops enough off the land to hardly make the presence of the unproductive crop felt.

FROM F. C. MILLER.

Nearly all kinds did well. For productiveness and good size Bubach, Jessie, Haverland and Crawford stand at the head. One picker in two hours picked twelve quarts of Jessies of superior size and quality. We sold over 200 bushels from a little over an acre and lost by rotting not less than 100 bushels. The Bubachs were immense in size, but the Haver ands out-yielded them. Crawford is the foremost and best in quality of all. The largest berry grown was a Crawford, but it is not quite as productive as I would like. Warfield is well liked; Burt not so well. I am greatly pleased with Bomba. It is productive, firm and of good quality. Monmouth was good and firm. The plants are not strong enough to mature all up to size. Gandy is a grand berry, but there were too few of them: all like its size and quality. Logan did well.

New Philadelphia, O.

The Poultry Yard.

POULTRY PICKINGS.

SEPARATING STOCK FOR FEEDING.—On the farm where the only incubator used is the old reliable hen, the flock of chickens is usually composed of birds of various sizes. Where they are fed together, as is generally done, the late-hatched and consequently the smaller and weaker ones are so crowded and run over by the larger, that they do not get their proper share of feed, and consequently make little if any gain. It is but a short job to make a covered pen of lath, old barrel staves, or strips of board, with spaces of sufficient width to admit the smaller chicks, and exclude the larger ones. Here they may be fed, and will soon learn to eat in peace and quietness. The extra gain made will well repay the slight expense.

GRADING UP.—Farmers are rapidly learning the importance of improving their horses, cattle and other stock, either by selecting the most desirable animals for breeders, or by crossing with pure-bred males, or both. The same principles should be applied in the poultry yard. The average farmer wants a hen that will lay a goodly number of eggs per annum; that will hatch a good brood of chicks under adverse conditions, and that furnishes a good carcass for the table. If he continue to breed in year after year, his stock will run out. To keep up the vigor and productiveness of his flock, new blood should be introduced. The best hens should be selected for breeders, preferably hens one year old; then—as the male is half the flock—buy a full-blood cockerel, (or more if the flock be large) of some desirable breed. *Now* is the time to attend to this matter. The flock needs culling now; breeders are anxious to sell their surplus stock at this season. Many times cockerels with some defect of plumage or coloring can be bought at low prices, and are just as good as "standard" fowls for improving common stock. This is the cheapest and best method for those who do not care to keep pure-bred fowls.

The hens should have extra care and feed during the moulting season if they are expected to do their best afterward.

Put some clover in the silo for winter-feed for the hens. A tight barrel or large box will do, if the clover is tramped down tightly and well covered.

For winter-layers, the early pullets and early-moulting hens are most valuable. Eggs are usually worth most in early winter, and then is the time when we want the hens to lay.

RAISING CAPONS seems to be a growing business, and there are many inquiries in relation to the process of caponizing. This is a cruel operation to say the least, as is evidenced by the fact that from 10 to 25 per cent. of the birds are said to be killed by it. No one should undertake to perform it but an expert, and then only when provided with the best instruments obtainable.

Milk and butter-milk are excellent for both laying hens and growing chicks.

Eggs, *if perfectly fresh*, may be packed in salt, bran, oats, etc., and kept in good condition until mid-winter. Pack so that they will not touch each other, keep in a cool, dry place, and turn the package every few days. They will keep better if the hens have no male companions.

If the nests haven't received attention, it is more than likely that they are swarming with mites. The nests should be movable, so that they can be carried out-of-doors Pour a little kerosene over the straw, or other nest-material, touch a match to it and let it alone. It is good for the hens, although rather warm for the mites. Do you know that nice, new, clean nests encourage hens to begin laying? Fact!

Everywhere.

VERMONT NOTES.

Decadence of sheep husbandry; butter tests and prices; hay; wood for fire; bee-keeping; no "quid pro quo" stone-walls; happiness on slim means; the spruce as an ornamental tree; scarcity of evergreens and young men about farm houses.

"THE sheep on a thousand hills" where, oh! where are they? The hills are here; even the sheep-paths may be traced along their sides, but the sheep have disappeared; gone I fear never to return. The primitive forest is gradually reclothing the land reclaimed from it by the early settlers. The "bush" so recently driven far up the mountain sides is again covering the valleys and is working its way slowly toward the villages. What is to be done about it? Some say the tariff on wool is too high; others say it is too low, and a few think it would be better to have no tariff at all. I am inclined to think that the temperate climate and rich grass of North Carolina and the South Western States with the low-priced labor, give rise to too strong a competition in the production of wool for northern New England, with its long, cold winters and high-priced labor. It pays so much better to haul and cut marble than it does to raise sheep that there is little hope of a revival of the sheep growing industry.

Corn came up badly and will not be over two-thirds of an average crop; but with meal from the West selling, at this season, for $18 per ton, it would seem to make but little difference whether the crop was a failure or not.

The remarkably low price of butter is working serious injury to the average farmer. I notice that many farmers attribute this to the modern system of co-operative creameries. They say that creameries have ruined the sale of home made butter and lowered the price of the product of the factories, but of course there is nothing for them to do but to grin and bear it. Shall cream be paid for according to its bulk, or shall its value be determined by the oil-test churn? This is the question which is seriously disturbing the minds of the patrons of the creameries. It is evident that all cream is not alike; that given bulks of Guernsey and Holstein cream will not produce the same amount of butter. The question is, will the oil-test churn determine accurately the actual amount of butter which each will produce? Some experts say it will; others say it will not. At any rate the oil-test churn is coming into very general use and is giving very good satisfaction.

The hay crop is enormous, but the extremely wet weather has prevented its curing in good shape. In many cases it was left standing too long. The markets must be glutted during the coming winter with poor, discolored hay. The new hay presses enable the Vermont farmer to send hay to New York and Boston and compete with the local farmers. This relieves the home market somewhat and it is probable that there will be a ready market for the surplus hay; but at very low prices. Some of the farmers are holding on to their cattle and think it will pay to feed out the surplus fodder.

The old New England custom of attaching the carriage-house and wood-shed to the dwelling-house is not without its advantages even at this season. The housewife is pretty sure of plenty of good dry wood without going out-of-doors for it. The horses, too, get better care than they would if they were a quarter of a mile away. Wood-burning engines seem very odd, yet it is a positive pleasure to ride behind them. The smoke at times is a trifle unpleasant, but they are vastly more agreeable to the traveler than the soft-coal engines so common in the South and West. It is astonishing how the supply of fire-wood on the hills of Vermont holds out. In fact, the supply of wood seems to be increasing instead of diminishing.

Bee-keeping is becoming quite an important business. Unfortunately the weather has been most unfavorable this spring. It is hoped, however, that high prices will prevail since the demand for honey is on the increase

A good many farmers have taken what are called "fresh-air children" during the hot season. It seems very odd for a wealthy city like New York to accept for its children the hospitality of the comparatively poor farmers of New England. How many wealthy New Yorkers would open their brown-stone mansions during the winter to the poor country children?

Miles and miles of stone walls, representing months of hard labor adorn (?) the hills to no purpose. In many cases they only serve as boundary lines and are not of the slightest use or value. The most docile animal can walk through them almost anywhere. Being built of stone, these fences, if such they may be called, will remain lasting monuments of the folly of a past age.

How do the people in the poorer parts of the State get a living? They cultivate only an acre or so of ground, and keep but one horse and possibly two or three cows. In the winter they earn a little money cutting firewood. So the years come and go without their handling perhaps $50 in cash during the whole year; and yet these people are in most cases contented and happy. In fact, I believe there is more happiness per capita in the State of Vermont than there is in the city of New York.

Some of our landscape gardeners might learn a valuable lesson in the hills and valleys of the State. The spruces never look so handsome as when scattered over their native hills. Let him who criticises the rough and hardy spruce, see it as it grows wild among the rocks of New England. It is utterly beyond criticism; it makes the finest landscape effect to be found anywhere in the world. It is graceful in shape and beautiful in color, but its chief attraction is the unique way it has of growing with the utmost abandon and in the oddest sort of places.

Strange—isn't it?—that in localities where such beautiful evergreens as the arbor-vitæ, Hemlock-Spruce and the White Pines grow to perfection along the hillsides and river bottoms, they are seldom seen about the farm houses.

Where are the young men? It is very seldom we see any but old men and boys at work in the fields. Will foreigners buy the old homesteads when the old people are dead and continue the work, or will the land grow up with brush, and the houses and outbuildings go to decay? RAMBLER.

RURAL SPECIAL REPORTS.

Canada.

ST. HENRY OF MONTREAL August 2.—Potatoes in this section have all been stricken with blight and are rotting badly. The last to succumb was the R. N.-Y. No. 2. They had a very fine appearance with stalks one inch in diameter near the ground. The tubers are large. The potato beetle has been very troublesome this season, the rain washing off the green shortly after it was applied. Apples are a light crop and badly spotted. The only kinds that are free from spots are the Duchess of Oldenburg, Yellow Transparent, Golden Russian White, Wealthy and American Golden Russet. I have tried spraying the trees with flowers of sulphur and also have tried burning the stuff amongst the trees; but it happened to be in seasons when the apples did not spot any where. Seasons that are too cold and wet to produce corn and tomatoes will tend to cause the spots on apples. One year out of 300 barrels of apples I had only 10 free from spots. The next year it was hard to find any that were affected in this way. Altogether it is a blue outlook for the farmers—potatoes rotting, oats rusting, no wheat, and weather too wet to save the hay. We will have to economize to make both ends meet. B. B.

Delaware.

DOVER, Kent County, July 27.—This has been one of the most trying seasons for farmers in years. The usual pressure of work through our working season has been lately increased by the extraordinary wet season and otherwise unfavorable weather. I think that it has been too wet to work our crops at least one-third of the time since planting, and the effect of the wet season will be felt for the next year. Delaware has a vast amount of low land that in a season like the present will scarcely return the seed. In riding through the country one sees hundreds of acres of corn that will not yield five bushels to the acre. Although corn on high land will make a crop, the State will produce little, if any, more than will be required for home use. The hay crop was good, but a great amount was damaged more or less in curing. Early potatoes are a good crop. In a few small sections there will be a full crop. The peach crop will be very light; many large orchards that would have been good for thousands of bushels under favorable conditions will have scarcely more than enough to supply their owners. Pears promise well, although troubled some with blight. Apples are not very plentiful, with a good home market for the same. Early truck is about gone. Sweet corn and early tomatoes are in the market. The shipment of blackberries has been very heavy. Wheat was a fair crop, but much of it has been damaged, as since harvested the weather has never been dry enough to permit thrashing for over two days at a time. Usually wheat is all thrashed before this. The machines have been out four weeks with an average of three days' work a week, and machine-men are about ready to quit in disgust. The present indication is that the bulk of the wheat will go on the market in poor condition. That marketed at present, brings from 60 to 80 cents per bushel. Pasture is usually good, but stock are losing flesh as the flies are unusually bad. The rose-bug destroyed nearly all the grapes. Farmers are plowing for wheat. The tomato crop promises to be good and the factories will start about the middle of August. Corn 40 cents; wheat, 60 to 80 cents; oats, 30 cents; potatoes new 40 cents; butter, 20 cents; eggs, 15 cents; apples 40 cents. A. G. S.

New Hampshire.

MILFORD, Hillsborough County, August 5.—I see by the RURAL that the country at large is well watered. We have had so much rain that haying has been very uncomfortable so far; but most farmers have nearly done on high ground; but there are acres of low ground that have not been cut, and if this weather continues the hay there will have to be abandoned. The oat crop about here is a total loss, as oats cut 10 days ago are flat on the ground; those cut earlier for fodder lay flat 12 days, but have not been hurt so badly that they cannot be used. One neighbor who sowed 30 bushels for fodder rather late, has not cut the oats as yet, and they are lodged badly, and I would not cut them if he would give them to me.

Potatoes are rotting somewhat and some pieces emit a very unpleasant odor. The Rural No. 2 is looking nice so far, but I noticed to-day that the plants were covered with the old beetles. I should say there were 200 of them on four hills; there are none to speak of on other kinds. Lima beans are white with bloom; they never looked so well. Golden Wax are spotted so badly that they are unfit for use. White pea beans are spotting now, but other crops are flourishing, especially vines of all kinds, and corn. The second crop of clover is ready to cut; so is millet, but the weather is too wet to dry it. P. C.

DOVER, Stafford County.—POTATOES.—This has been the hardest season for farmers that we have seen for a long time. The weather interfered with planting and hoeing. Potatoes were, however, looking well, with the promise of a good crop; but now it looks as though the yield would be poor and small. Two weeks ago, the tops were green, but the wet and muggy weather has rotted them. Now they are nearly all dead and the odor that rises from potato fields is sickening. There will be a fair crop on some early pieces, but they are rotting and store-keepers will buy only a few at a time. For a number of years I raised some Early Rose Potatoes which I dug the 7th of July, averaging a bushel of handsome, marketable tubers to 12 hills. I thought I was going to equal that yield this year, but the weather has beaten me. My R. N.-Y. No. 2 was planted later. One good sprout came from it and I planted it whole. The tops had gone like those of the others, and so I dug them to-day, for fear they would rot. I got four handsome tubers which weighed two pounds and thirteen ounces. One of them weighed seventeen ounces. For three or four years past I have raised Clark's No. 1, and like them better than any others, as they cook and keep better than others. On the 20th of July we cooked some of the old ones and they were as good as when they were dug. White Elephant yields better, but rots badly.

HAY.—There was a good crop of grass, but most of the hay will be poor. Many of the farmers do not begin haying soon enough; but will wait until after the Fourth of July any way. A few who began when grass was ready to be cut got most of the hay in pretty good shape; while many have now not done half the work. At present a great deal of hay that has been cut more than a week, is out on the fields, and the grass has started around the bunches so that it makes quite a show. When will farmers learn to begin haying earlier, and that six men are worth more in one good hay day, than one man in six days? Corn is looking pretty well, but it is backward. Oats were good on high ground; but not so good on low.

STRAWBERRIES did not do well with us this year. It was so dry last year that the plants did not run very much. They have run well this year, so next year we shall be able to have a full ration, (which will be as large as Fred Grundy's or larger) and some to spare. Other berries and Red Astrachan Apples are plentiful now. Good fruit, good air and plenty of work can be had on a farm—and what else do we need?

CORN FODDER.—For cutting fodder corn, take a light cleaver and you will like it. When the fodder is long, when you get it to the barn, cut it three or four times with a broad axe. The cows can eat it better

W. E. R.

New Jersey.

TRENTON, Mercer County, August 5.—As the wet weather seems to be quite general, I suppose I will tell you nothing new when I say it has been very wet here. Eight out of 10 days have been stormy, the rain much of the time pouring down. During Saturday the 3d the rainfall was especially heavy, accompanied with much lightning and heavy thunder. July also was an unusually rainy month. The rainfall amounted to nine and eighty-six one-hundredths inches. The average monthly rainfall is about four inches. On 15 days during the month there was rain, and nine days were cloudy. The effect of so much wet weather and the absence of much sunshine are seriously injurious to all agricultural interests. Work of all kinds on the farm is almost at a stand-still. Crops, such as oats and hay, are unharvested and in the more northerly sections of the State they are ruined. Corn is bent, and a full yield is now out of the question. I do not believe the State will average 50 per cent. of a full crop. Though the hay crop was good, much of it was poorly secured. Some—in many cases most of it—was stacked out. This, owing to the continuous wet weather must become seriously injured. Wheat is far from being a full crop.

As to potatoes, I have made quite an extended trip amongst some of our largest potato growers in the vicinity of Freehold, Monmouth County, and found whole fields in which there were only exceptional spots free from the advancing ruin. The vines have blighted within a very few days as though a fire had run through them. Varieties almost ready to dig were not more affected than later sorts that were but half grown. They all show the blighting influence of some general "epidemic." One or two of the newest varieties, it is hoped, may escape the rot, though it is hardly likely. The prospect for overproduction is not flattering. Tomatoes cannot set and melons will be a failure. Peaches, where there are any, will crack and rot. Of course, all these adverse circumstances cause loss and discouragement to the farming community. But others are also feeling the effects of this condition of the weather. Laboring men, carpenters, and masons especially, are losing much time. The building boom which has been going on in this city for the last few years, still continues. It is remarkable. But, while houses by the score in every part of the city have been begun, their completion has been very much retarded by the continuous rains. Mechanics come with their dinner pails to put in a day's work, only to return after an hour or two without having done a stroke. Unless they can make time, they must live more economically, and this means a more limited market for farm-produce as well as for other things. If the old adage "The first three days rule the month," prove correct, we may expect August to be wet; but we hope for the best. Meanwhile let us take good care of what we have; guard against wastes; improve the time and the mind, and we will pull through. F. D.

New York.

FORESTVILLE, Chautauqua County, August 1.—Haying has come and gone. A finer season for cutting and curing hay was never known, it being cool and sunny—good weather for both hay and workmen. The quality of that cut has been fine and the quantity larger than was anticipated at the time of the big frost in May. Oats are the largest and best of the kind ever grown in this section. The stand of corn is poor. Potatoes are looking fine and promise to be a large crop here. Barley is about half a crop. It is too wet for it this season. Apples are a total failure and other fruits are found only in small quantities.

Nearly all kinds of farm produce are selling low: butter sells at 13 to 15 cents per pound, while cheese brings eight to nine cents per pound; eggs 13 cents per dozen; hay and straw on the decline. Business slow and dull.

C. H. F.

SOUTH BYRON, Genesee County.—We have had an abundance of rain. Wheat, barley and hay are excellent and harvested in good condition with the exception of a part of the last. The apple crop is very light. There is a partial crop of pears in some localities. Potatoes are generally poor, with occasionally a good field. Oats a heavy growth where not too wet; but not yet harvested. I. D. C.

North Carolina.

MCKEE, Davidson County, July 30.—We are having an excess of rain. Wheat about like last year; corn on low land almost ruined by high water, but on high land better. Fruit an abundant crop, but peaches are rotting on the trees as fast as they get ripe. G. W. B.

THE FARMERS' CLUB

ANSWERS TO CORRESPONDENTS

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see if it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

AGRICULTURAL COLLEGES: SHEEP HUSBANDRY.

E. H. C., Oberlin, Ohio.—1. Which is the best agricultural college in the East and which in the West? 2. Would it be advisable for a man 33 years old to take a college course? 3. Where could I learn sheep husbandry to the best advantage? 4. What State is best adapted to the business?

ANS.—1. In the East, Massachusetts, at Amherst, Mass., or Cornell, Ithaca, N.Y. At the first-named place you can probably get a more satisfactory general course, while at Cornell you can doubtless find better facilities for special instruction. There are fewer students at Cornell, consequently better chances to obtain special work on the farm or personal instruction from the professors. In the West, Michigan, Iowa or Kansas. 2. There are many studies in the agricultural college course that are intended for younger men or boys. A man of your age probably would not want to go through the mathematics, rhetoricals, etc., etc., that might be more useful to a boy. The chemistry, botany, entomology, physiology and physics would help you in the study of practical agriculture. The R. N.-Y., on the whole, believes it would pay you best to go to a college like Cornell or Wisconsin, where, with men like Prof. I. P. Roberts or Prof. W. A. Henry, a special course could be taken. We firmly believe that a man 50 years old can learn something at these colleges if he goes to them prepared to learn. 3. The best way to learn the principles of sheep husbandry is to hire out to some good sheep-breeder, and study and work at the same time. It must be remembered, however, that a life-time is all too short in which to learn all there is to know about sheep. 4. This will depend upon the class of sheep you wish to raise. For mutton or early lambs it pays to get near a large city where the markets can be easily looked over and advantage taken of a low price for buying or a high price for selling. If you want to raise wool you should search for cheap lands with good pasture and water supply. At present we should say that Montana offers the best opening. A year spent as a sheep herder on a Montana ranch before you start for yourself, will be invaluable.

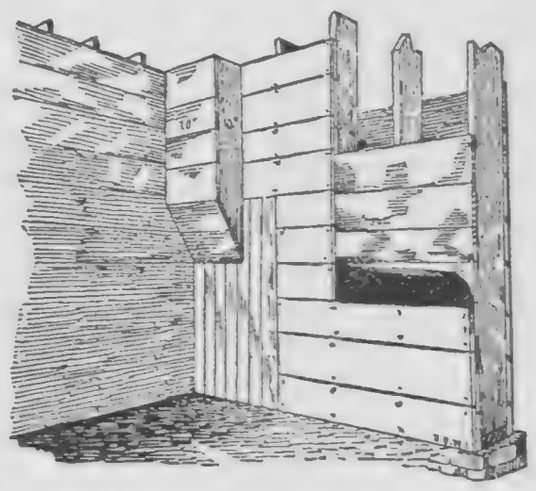
Miscellaneous.

J. W. N., Stowe, Vt.—What is the address of the American Dairyman, and the Dairy World?

ANS.—The American Dairyman, New York City, and the Dairy World, Chicago, Ill.

D. J. P., Sherburne, N. Y.—How can I get rid of live-for-ever?

ANS.—We should be glad to learn from our readers as to the most economical way of exterminating this pest. There is said to be a contagious disease affecting this plant which, when introduced, spreads and destroys it rapidly.



SILO CHUTE Fig. 206. Page 543.

C. F., Fort Wayne, Ind.—Is there any work on frog culture? How are frogs grown for market?

ANS.—We do not know of any such book. Frogs' legs find ready sale in New York. The price paid now is 25 cents per pound. The RURAL hopes to prepare an article on this subject. From investigations made thus far, it appears that all efforts to breed and raise frogs as a business have failed. The frogs that come here are mostly caught in ponds and rivers in the northern part of N. Y. State.

A. A. G., Northville, Tenn.—1. Should young apple trees that are eaten by locusts be cut back? 2. Which is the earliest strawberry? 3. What is a description of, the August Giant Grape?

ANS.—1. It depends upon the amount of injury sustained. The wood covered by new bark will not necessarily become decayed. It will be protected from rot by the bark in a measure. 2. We can't say which is the earliest. Monmouth, Crescent, Crystal City, May King are among the earliest. Crystal City has little merit beyond its earliness. Parry begins to ripen very early. 3. The R. N.-Y. has never raised this grape. It is said to be a cross between Marion and Black Hamburg. Bunches large, berries large, oblong; pulp tender with the Hamburg flavor. Leaf strong and thick. Vine hardy. The R. N.-Y. has heard few favorable reports about it.

DISCUSSION.

WILL AMERICAN SUGAR PAY?

A KANSAS FARMER.—Inclosed find clippings from the Kansas City Journal which makes some pertinent inquiries about the sorghum business. More than a year ago I gave the RURAL my views about this matter, and they have undergone no change. The scheme has

been to pocket as much public money as possible, secured from the nation and the State, as well as counties, townships, cities and such gullible innocents as can be induced to take stock, which will all be wiped out in a short time; but the few will have filled their pockets. The fact cannot be controverted that the raw material for the manufacture of sugar in this country, no matter what it is—be it cane, sorghum, beets, or anything else—can not be raised and handled at the present high price for labor in this country, and compete with the product of the unpaid or ill-paid labor of the islands of the ocean and other countries. When sugar can be laid down in our ocean ports for 4½ cents per pound after having paid the duty, what is the use of Americans trying to make it at a loss, even after the receipt of national and State help. If the time ever comes when we will have to make our own sugar in order to have any, we can make it from Maine to California, and from the Lakes to the Gulf; but not at present prices unless there be a fall in the current price of labor.

R. N.-Y.—The newspaper article referred to discusses the probable profit of sugar-making in Kansas. It appears that efforts have been and are still being made to locate sugar mills in the sorghum-growing sections of that State. The plan pursued was explained in the R. N.-Y. two years ago. The town where the factory is located is to provide the necessary money and the factories are to be operated by experts who take part of the stock besides good salaries for their services. Several towns have already raised in the aggregate $500,000 for the purpose of starting these factories, while as yet there are no official figures to show that the business is certain of yielding a profit. The article goes on to state that no figures have ever come from the factories at Fort Scott, Topeka or Conway Springs to show that they have ever made any profits or even paid expenses. It is also claimed that as soon as the new factories start up, Prof. Swenson, who claims to own a patent on the process to be employed, will commence suit for infringement, which suit will involve great expense.

A. M. Bonebrake who is connected with the Fort Scott Mill, is quoted as saying that the mill paid running expenses, but not the expenses and interest on borrowed capital. He says there will be no money in Kansas sugar until a refinery is established at Kansas City or some other central point, that can use the sugar for refining and utilize sirups. Ten mills like the one at Fort Scott can give business to such a refinery. Though not having much to do with the sugar business, the following extract from this gentleman's remarks is interesting:

"Kansas has been a State of waves on money-making, but the waves recede too rapidly for the man who desires a permanent investment, and fortunes have been lost because the infection became general. The Kansan is yet numerous who invested his all in wheat-growing, and wheat kings sailed high until their aerial ship burst, and down they came, pauperized. There was the sheep disease, which spread so rapidly, and took such serious hold that there is not a county in the State but is the home of men who had visions of a trip to Europe on the proceeds of mutton and wool, but they did not go. Then came the era of silver mines in Colorado in which were buried more than $3,000,000 of good money, for which five figures would represent all the returns. The people in Colorado fattened upon the money of people who would get rich in a short time, and who, in their fancy, traveled only in private cars, with uniformed servants to wait upon them. The town-lot mania is of recent date, and while many grew rich out of speculation, very many more "hung on" just a little too long, and are owners of fine farm property, if they only had enough of it.

Through all these stages the money loaners thrived and prospered, and demonstrated the wonderful resources of Kansas, which has continually advanced and grown rich in spite of these drains upon the people—the speculative portion of them."

HOTEL SWILL: HOW IT SHOULD BE USED.

Col. F. D. Curtis, Saratoga County, New York.—A writer in the Rural on page 477, very properly commends "hotel swill" as an excellent food for swine. These gatherings from the kitchens and tables of hotels and boarding-houses contain a great variety of food, and, as a rule, the mess is well balanced; that is, made up of very good proportions of the nitrogenous and carbonaceous elements. Fed in limited quantities, it will promote a healthy growth; or, if fed liberally, it will fatten hogs rapidly. It is well calculated for either pigs or older swine. When there is a stinted supply there is rarely any trouble; but when the supply of "swill," exceeds the daily wants of the hogs, there will be disease. The cases of extensive mortality among hogs fed on hotel swill are numerous. They are usually charged to "hog cholera," and after the hogs are all dead and the neighborhood has ceased wondering how this epidemic got among them, the thing is tried over again with similar results. The second experiment in attempting to keep the hogs on this food, is usually the last. At Willard Asylum in New York State, a few years ago, death took all the hogs which were fed on the aslyum swill and the same thing occurred at the Northampton, Mass., Asylum. The hogs fed from the swill of the large hotels at Saratoga, have, at different times, died, and also those fed on the slops from other large establishments. In all hotel swill there is a great deal of starchy food—bits of bread, pies and pudding wastes. These remnants ferment rapidly, and become the foundation for an active and general ferment of the whole mass. In hot weather they will ferment in a few hours, or perhaps right away, and especially as the fresh swill is kept in the same vessels from which the old has been taken, and these retain the germs of ferment. Under these conditions these starchy and the sugary portions of the swill become active irritants in the stomachs of the swine, or reach such a degree of fermentation as to become poisonous. This kind of food-poison, from day to day, soon produces scours, and then dysentery or cholera, as it is called, and the hogs die. There is in the swill another kind of food which is even worse in its effects than the ones I have described, and that is the meat. This is mixed all through the swill, and is acted on by the germs of putrefaction, and in this state it is eaten by the swine. Putrid meat is also inflammatory and poisonous. The hogs eating this kind of food, day after day, are sure to be taken with a malignant dysentery—"cholera"—and to die very soon. All of this trouble is unnecessary and if my suggestions are adopted, it can be readily avoided. At the asylums and hotels mentioned, all hotel swill and house gatherings should be fed before any fermentation or putrefaction takes place. It should be gathered twice a day in hot weather and no more should be given to the swine than they will eat up clean at each meal. The residue should be *buried* where the hogs cannot get at it. The vessels in which the swill is collected or transported should be changed every day and thoroughly washed out. The hogs should have access to the ground, and they should have all the coal ashes, cinders and salt they want. The coal ashes can be dumped into their inclosure by the load and the salt kept always in a tight box where they can get what they want. Where these precautions are taken there will be no dysentery, and the best of pork can be made. Too many hogs should not be kept together, especially in a close range. The smaller ones should be by themselves—15 or 20 in one bunch are as many as should be together. There should be a shed under which they could lie out of the sun and storms. The bottom of this should be dry, the troughs should be kept free from mud and filth. A great deal of valuable food is often allowed to go to waste for lack of management of hogs on common-sense principles.

"POSITIVE KNOWLEDGE."

A. L. C., Catonsville, Md.—"A Cooley Man" says: "I know that cream from various sorts of milk raised in the Cooley, when run according to rule, and the divisions made by spaces, comes nearer to yielding all the contents of butter fat in it than that raised by any other device." That is a strong statement and one would naturally suppose that a "Cooley Man" had tried all other devices for raising cream. It is very satisfactory to have such positive knowledge; but we ought to be sure we have it before we make such strong assertions. Some years ago I set my milk in submerged cans in a tank of ice-water; the result, so far as the cream was concerned, was satisfactory; but the labor of lifting out the cans for skimming was not, so I bought an Occident Creamery, which was much more convenient and saved much labor. I had a prejudice in favor of submerging the milk, and did not expect any better results from the change, so I was very pleasantly surprised to find that the butter showed a gain of exactly 50 per cent. at the next churning. I attributed this gain partly to the variation in the yield of milk, but it continued, and I was forced to the conclusion that submerging milk was not the good thing I thought it was. Now how does "A Cooley Man" explain this gain if he "knows" that the cream raised in the Cooley comes nearer to yielding all the contents of butter fat in it than that raised by any other device? I cannot explain it, as I "know" so little about these things that I am always ready to have my opinions upset at any time and in many ways. I am trying to learn what I can though, and have lately been weighing the cream to see how many pounds it took to make a pound of butter. Prof. Babcock said recently, in the Jersey Bulletin, that it required about 6½ pounds of cream raised in a Cooley Creamer to make a pound of butter. This he said in arguing against the claim that Jersey cows had made a pound of butter from—well, say less than 10 pounds of milk. The result of my weighing has been that at four different churnings, I made one pound of butter from 3½, 3⅛, and 3⅛ pounds of cream and the last time from a fraction less than three pounds of cream raised in the Occident Creamery. I suppose Prof. Babcock got his "know" from several different tests, and "A Cooley Man" must have got his "know" from trying all the devices used for cream-raising; my "know" comes from only four trials and I expect to make the fifth tomorrow, and will not be much surprised if there should be much difference in the result. I will say that my cream is from the mixed milk of nine cows, so that the freedom from water in the milk cannot be attributed to one phenomenal animal.

ABOUT SLUG SHOT.

Benj. Hammond.—Regarding recent statements in the R. N.-Y. as to "Slug Shot," it is a well known fact that the finer a powdered insecticide is made, the more effective it is. In order to get plaster as fine as possible before mixing it with the other ingredients that enter into "Slug Shot," it is first double-ground; that is, it is ground as fine as flour, and it is then bolted. These processes cost more than the plaster itself; in other words, the work more than doubles the cost of the plaster. In the next place, if potato beetles were the only insects for which "Slug Shot" was used, it would simplify matters very much; but it is used for a great variety of insects, and hence other poisons, such as tobacco, etc., have to be incorporated with it. This still further increases its cost. Then the fact is overlooked that three-quarters of the Slug Shot sold, is retailed in five and ten-pound packages, to people with small gardens, who have neither the time nor the skill to mix Paris-green with plaster. It takes only from 15 to 25 pounds of "Slug Shot" for an acre of potatoes if it is properly *dusted* on. Consequently, very few farmers buy it by the barrel. It is unjust to compare the cost of a barrel of plaster mixed with Paris-green with the selling price of a small package of Slug Shot or any other insecticide. Take, say, five pounds of the plaster and Paris-green; and put the mixture in bags nicely labeled; send it, say, 100 miles by freight; add to its cost two or three profits with the cost of advertising, and it will be found that it cannot be sold at a price less than that asked for "Slug Shot." In the potato-growing sections farmers seldom use insecticides in the form of a powder; as a rule, they use London purple and water, applied with a sprinkling machine. The consequence is that there is little or no demand for insecticides by the quantity in powdered form.

"CRANBURY FARMING" AGAIN.

D. C. L., Cranbury, N. J.—On page 510 of the Rural a reference is made by N. D., N. Y City to the articles published by the R. N.-Y. on our system of farming at Cranbury He assumes that I could not have over 40 acres in grass, and that at two tons per acre I could not sell over 80 tons of hay. The Rural's reference, on page 512, to my letter in answer to its questions should have answered all his objections except in one or two instances. I mowed last year 42 acres, and sold over 90 tons of hay. This year I mowed 38 acres and will sell without a doubt over 100 tons of hay. I do not feed my cattle any hay except in unfavorable weather when I have to house them through the night. The R. N.-Y. will remember the piece of grass near my outbuildings, containing about seven acres, that has been mowed for four years without the application of fertilizers of any description. I am quite confident the hay from it will weigh three tons to the acre. My wheat will this year yield over 30 bushels per acre, and my corn now bids fair to be a heavy crop. I cannot speak so confidently of my potato crop this year. I would not at this time estimate it at more than 175 bushels per acre, and if the present wet weather continues I may lose many by rot. I am told potatoes are rotting badly in Monmouth County, near here, and about Freehold. In reference to wintering steers, if we could buy them in the fall at prices corresponding to those at which we have to sell them in the spring, we could of course winter them at a profit.

SHALL BANANAS BE ADMITTED FREE OF DUTY?

J. M. Smith, Green Bay, Wis.—My general idea has been, and still is, that all tropical fruits and spices should be admitted free of duty, provided they could reasonably be classed among our necessary articles of food now in general use among the masses of our population. Bananas, pineapples, cocoanuts, etc., are not in general use, and are, in fact, but very little used except in our towns and cities, and even there, much the greater portion of them are used either by the wealthy or well-to-do classes. It is possible that the trade in our home-grown fruits may be slightly affected by the large amounts of these foreign and tropical fruits that are thrown upon our markets at certain seasons of the year; still I imagine that the increase, either in the sale or the prices of our home-grown fruits, would be hardly perceptible if they were entirely shut out of our markets. To sum up the matter in a few words: I think it very unjust to the great masses of our population to let the above-named fruits in free of duty and still keep up a heavy duty upon sugar, an article that is, or ought to be, upon the table of every citizen of our country. If I had the authority I should reverse the duties and do it immediately.

THE "GOOD" PEACH.

E. B. G., Manchester, Pa.—The "Good" Peach to which reference is made in the R. N.-Y. of August 3, originated about 20 years ago in the lot of the late Mr. George Allright, York, Pa. When the tree first came in bearing the fruit was so fine and attractive that Mr. Allright was induced to exhibit some at the county fair where it attracted universal attention. It was there that I first noticed it and I at once commenced propagating the trees and had no trouble in disposing of all I could raise right here in York; consequently the peach is not much disseminated, and is new to the outside world. It has of late come into the hands of several prominent fruit growers, who are enthusiastic in its praise. The tree is a very vigorous, healthy grower and abundant bearer. The fruit is of large to very large size, of a creamy white, sweet, melting and of delicious flavor, superior to any peach ripening at its season—the last of September to October. As to its reproducing itself from seed, I have no experience, but I am very doubtful, and no one should buy trees so raised under the impression that he will get the genuine "Good" Peach.

ACTINIDIA AT THE WEST.

Prof. J. L. Budd, Ames, Iowa.—I have just read in the Rural, with much interest, the notes on Actinidia polygama as grown on the Rural Grounds; but the impression should not be conveyed that this or any other member of the Camellia family will do well in the cold North, or west of the great lakes. With us the A. polygama suffers severely in winter, and in the open sunshine its foliage burns in summer, yet for a summer screen for shady porches and arbors we have nothing better, as it comes up quickly, and its foliage has the half-tropical aspect of the Madeira Vine. On the Rural Grounds, and near the coast southward, the Actinidia arguta will be apt to prove the handsomest and most useful species. As seen in arboretums in Europe, the foliage is larger, darker in color, and more shining than that of A. polygama, and the flowers are larger, more numerous, and pure white in color. In addition, the fruit is edible and agreeable in taste and flavor. The hardiest species is A. callosa of the Ameer region; but the foliage is smaller and less pleasing in expression, and the flowers are small and few in number.

What Others Say

AN EXPLANATION IN ORDER.

The following letter dated the 24th of July, has been received from Prof. C. V. Riley (United States Entomologist) now at the Paris Exposition:

Editor Rural New-Yorker:

Among the few papers which I have sent to me regularly from Washington is the Rural New-Yorker. In the issue for July 13th, page 463, you quote what you call a remarkable statement from me, published in the American Agriculturist. Will you permit me to say in the columns of the R. N. Y that I have not written a line to the American Agriculturist since Mr. Orange Judd went out of it. Hence I have made no statement in that paper, nor is the language which you quote, nor the impression which it conveys, in any way mine. It could not have been quoted from anything I have written, and therefore I disclaim it entirely. I have not seen the copy of the American Agriculturist from which it is taken, and am therefore unable to offer any explanation or solution of the matter. This is, of course, not the first time that I have been similarly misrepresented (even in your columns); but ordinarily I cannot find time to take notice of such misrepresentations. I have too much else to do.

While writing this note, however, let me also say that the article in the same issue, page 469, credited to Bell's Messenger and giving an account of the Agricultural Exhibition here in Paris, is really taken from an

editorial in the London Morning Post with some garbled passages. I believe it is very generally being copied and credited to Bell's Messenger, so that the error referred to is not yours. The editor of the Post was kind enough to give some credit, for the work *done*, to my co-laborers, Prof. Cheesman, and Mr. Charles Richard Dodge, and to myself as having had charge of the exhibit and as representative of the Secretary of Agriculture.

The Editor of Bell's Messenger can doubtless explain the matter. C. V. RILEY.

The following is the article in the R. N.-Y. of July 13, alluded to:

"PROF. C. V. RILEY makes the following remarkable statement in the American Agriculturist:

'The rose-bug is a hard insect to fight, and we have had no practical occasion to practice with it in the work of the Botanical Division of the United States Department of Agriculture. The old method was to knock the insects from the foliage or fruit into a pan of kerosene and water. This, however, is very slow work and not practicable on a large scale.

At River Edge, N. J., they found last season that a mixture of pyrethrum and water made a very excellent liquid to spray upon the vines. *It destroyed all of the insects which it touched and seemed also to have a preventive action. The proper proportion can only be obtained by further experiment.* Col. Pearson, of New Jersey, has also found that the original fungicide mixture of sulphide of copper and lime and water, sprayed upon grape vines, has *both a poisoning and deterring effect upon the rose-bug.* This insect is one which I hope to have a good series of experiments made upon with a view of determining just what is best to be done.'"

PROF. C. V. RILEY.

HARDY ROSES.—Of the newer varieties of Hybrid Perpetual Roses, says J. N. May in Garden and Forest, the best, so far in the locality of Summit, N. J., has been Mrs John Laing. Though not of a very hardy constitution, its pale-pink color, fine form and delightful fragrance make it a very desirable variety, and it is a splendid autumn bloomer. Earl of Dufferin is a grand rose of a deep bright crimson, very fragrant and of a good constitution. Lady Helen Stewart is another first class rose, with a good, vigorous constitution. Ulrich Brunner, though not particularly new, nor yet generally planted, is pleasing in shape and color. Queen of Queens has again proved one of the best bedding roses, of a pale shaded-pink color and very attractive in ever way. To Mr. May's mind, however, the best rose of this class introduced to this country this year is Gloire de Margottin. It is the clearest bright red yet introduced, very fragrant, a strong grower and a rose that pleases every one who sees it. Last of all is that grand rose, Madame Gabriel Luizet. With its satin-pink color and unsurpassed fragrance it has few equals, and it should be in every garden, no matter how small. If it were Mr. May's fate to be deprived of every rose but one for growing in the open air, he would choose this one above all others. It is still producing some good flowers, and will continue to do so all summer at intervals.

A CHUTE FOR THE SILO.—Professor E. M. Shelton, in Bulletin No. 6, of the Kansas Experiment Station, gives a description of a chute for emptying the silo. We give the picture at Fig. 206. We quote Prof. S.'s description as follows:

"The operation of feeding from the silo is usually performed from the door, as shown in the cut. In feeding, it is well to remember that if a silage surface is left exposed to the atmosphere for a number of days, it molds quite rapidly and not unfrequently a considerable loss results. On this account I prefer to feed from the top of the silage, so that more or less of the entire surface can be fed every day. To accomplish this purpose I have planned in the new silo, the chute, shown in the cut, over the door of the silo. This consists simply of a 2x10-inch plank spiked on edge securely to the silo, 20 inches from the corner. Twenty-inch pieces of shiplap lightly tacked to this projecting plank connect it with the adjacent wall, thus forming a 10x20-inch chute which passes through the inner door of the silo. We expect to shovel the silage constantly from the top, emptying the silo through this chute. As the silo empties, the pieces of shiplap may be removed, thus saving the lifting of silage to the top of the chute."

SHORT AND FRESH.

OUR friend (and every one else's friend as well) Dr. F. M. Hexamer, objects to the use of powdered pyrethrum or "Buhach" for destroying rose-bugs because "it disfigures the roses nearly as much as the beetles do." But why use the powder? It must be blown upon the beetles through a pair of bellows and this is hard, tedious work unless merely a few bushes are to be dusted. Why not spray the bushes with pyrethrum water? In this way a hundred roses may be sprayed with scarcely any laborious effort in the same time that would be required to dust a dozen, while one-tenth of the amount of pyrethrum would serve. As this powder is worth at least 75 cents a pound, the difference in cost might, also, well be taken into the account. Two table-spoonfuls added to two gallons of water will suffice for about 100 rose-bushes, while neither the foliage nor the flowers are harmed in any way.

THE New York Agricultural Experiment Station concludes that for the greatest amount of nutriment, considered from a chemical standpoint, corn should not be cut for the silo before it has reached the milk stage of the kernel. That it remains for future investigation to determine whether it is better to be cut at the milky stage or at a later period for the greatest amount of digestible and available nutriment.....

EXPERIMENTS made during the past seven years by the above station with Alfalfa lead to the following opinions or conclusions:

1. That Lucerne or Alfalfa may be successfully grown in New York State.
2. That when once established it thrives well upon clay land, but will probably do better upon good light loam.
3. That seed two years old loses its vitality and fails to germinate. Undoubtedly many of the failures to secure a stand of plants may be traced to poor seed.
4. That the seed-bed must be well prepared, and, in this latitude, it seems best to plant out the seed in the spring, and with no other crop. The seed should be but lightly covered by rolling the ground.
5. That for seven successive years at the station three and four cuttings per year have been taken from the plats.
6. That last year, the sixth in succession, the plats yielded more than 15 tons per acre of green forage, equal to 5.6 tons of Alfalfa hay.
7. That Alfalfa should be cut in early bloom, before the plants become woody.
8. That it should be cured largely in the cock to produce the best quality of hay.
9. That by chemical analysis the hay was found to be more nitrogenous than good Red Clover.
10. That cattle, sheep and horses all relish the hay and seem to do well.
11. That it is found to be more digestible than Red Clover hay.
12. That if farmers would try this crop we advise them to begin with a small piece of well-prepared land, in order to see whether Alfalfa does as well with them as it has at the station.....

THE most casual reader cannot have failed to notice the extensive and increasing investment of English capital in American enterprises and securities. Many fear that this bodes ill to this country, but the American Economist takes a different view of the matter. It says that the fact that it would be within the power and the right of the United States to confiscate the property in this country of any citizen of a State at war with the nation will prove an irresistible argument for peace. A thousand millions of English money invested in the United States would go far toward paying our part of the cost of a war with England .....

THE discarding of all early varieties of peaches for commercial purposes is urged by Colman's Rural World. If the Hale's Early and all other varieties preceding it were rooted out and destroyed and no more of such planted, it would prove a wise step, and beneficial results would follow. These early varieties are too perishable to ship any distance. They are wholly unfit for either drying or evaporating, and have not, in fact, a redeeming feature. They come into every market when there is no room for them, during the small-fruit season, and depreciate the value of other fruits, while the peach shipper never realizes anything for his shipments. A few trees for family or local use are admissible, but none should be cultivated for shipment. Each year demonstrates more forcibly the folly of raising and shipping such fruit, and the results of the present season show, as usual, that only the express companies profit by shipments of these early varieties. More late varieties and fewer early sorts should be the motto of every man who expects to realize anything from peach growing.....

PROF. MAYNARD of the Massachusetts Experiment Station, concludes from his investigations that as between cloth and glass as covering for cold-frames, etc., there is less danger of injury from sun-burning, and of a too great accumulation of heat with the cloth than with glass, and consequently less care is needed in using beds covered with this material during the day. At night, however, more protection is needed to keep out the cold.

In his experience the cloth sash is especially valuable for beds of recently transplanted plants, as the light is less intense and the evaporation less than with glass.

The cloth frame may be made at a cost of about one-sixth that of glass.

TO DISCOVER some means of hastening the fruiting of tardy-bearing trees or those that have grown largely to wood, a row of crab-apple trees was girdled. Three trees were girdled by cutting out a ring of bark one-eighth, one-quarter and one-half inch wide *at the ground*, July 12th, 21st and 29th.

Three trees were girdled just below the main branches with the three widths of girdle as in the first, July 12th, 21st and 29th.

The same as above was made on one or more main branches with the three widths of girdle, July 12th, 21st and 29th.

The results were that all the girdles made near the ground healed over readily and completely.

Those on the main trunk healed less completely, but sufficiently to ensure a good growth of tree and the covering of the injured part in another year.

The girdles made in the branches healed less completely than the last, and in two instances the new growth failed to meet and consequently the branches died soon after starting growth in the spring.

All showed a marked increase in fruitfulness over those not girdled.

Little difference was observed in the effect of the girdling made at different times or in the various widths of the ring of bark taken out.

AS REGARDS the poisonous effects of White Hellebore so commonly used to kill currant-worms, etc., Prof. Maynard quotes Blyth as follows: "20 grains of powdered root have caused death, and, on the other hand, ten times that quantity has been taken with impunity, so that at present it is quite an open question just how much may prove fatal." It is probable that the powdered root loses its active principle with age, and becomes not only less poisonous, but also less valuable as an insecticide.....

BLYTH in his "Poisons, their Effects and Detection," states that the following doses of arsenic may be considered as dangerous: two grains for an adult, thirty grains for a horse, ten grains for a cow, one-half of a grain to one grain for a dog.

There are numerous cases on record of recovery after enormous doses. In nearly all these cases, however, two conditions are recorded: first, that the poison was taken after a full meal, and secondly, that very early and free vomiting occurred. This, indeed, is doubtless the explanation of many cases which otherwise appear inexplicable....

WOODMAN and Tidy, in their work on Forensic Medicine and Toxicology, advise the administering of hot milk and water, and "emetics of sulphate of zinc or mustard; at the same time the throat should be tickled with a feather, but in no case should antimony be given. After free vomiting, give milk and eggs. Sugar and magnesia in milk is a good mixture, an insoluble compound with arsenious acid being in this way formed."....

PROF. MAYNARD finds the Lawson Pear very much like a variety called Early Harvest from Kentucky. This has fruited at the Massachusetts Station and answers the description of the Lawson (or Comet).....

PROF. MAYNARD finds the vine and foliage of the Eldorado Grape vigorous and good, but it is too late in ripening. The Eldorado is a very early grape—earlier at the Rural Grounds than Lady. Possibly he has not the true Eldorado. It is such a splendid grape where it succeeds that it should be thoroughly tested everywhere .....

Horsford's Acid Phosphate

Makes Delicious Lemonade.

A tea-spoonful added to a glass of hot or cold water, and sweetened to the taste, will be found refreshing and invigorating.—*Adv.*

WORD FOR WORD.

——VERMONT WATCHMAN: "Unlike his rather too high-toned predecessor, Dr. Collier has sought not to take his own way, or follow his own preferences, but he asks what it is that the farmers of the State want him to do, and tries to do it. He is a man of the people, bred up on a New York farm, and educated in science as a pupil, and a favorite one, of America's first and greatest agricultural chemist, Professor Johnson of the Sheffield Scientific School at New Haven, Conn."

——ORANGE COUNTY FARMER: "Party lines should have no influence on the farmer's vote. No matter on what ticket his name appears, support the man who has been found true to the farmers' interest; scratch the man who has been found wanting, and demand a pledge from all new candidates."

——FARMERS' REVIEW: "Any work, however humble, is better than to be a deadhead and a deadbeat, which is the usual fate of those who feel too good for their business."

——BREEDER'S GAZETTE: "In all his work Prof. Shelton has met with a large degree of success and has won for himself a high standing among educators of the country. By the way, it is a little odd—but none the less gratifying—that a dependency of Her Majesty should appeal to the American Government for an instructor in agriculture. Evidently 'Yankee' methods of farming and stock-breeding are appreciated abroad."

——HUSBANDMAN: "When farmers establish a trust and stay by it, other people will starve."

——N. Y. TIMES: "It is a matter of history that inventions which have eased labor, have increased wages and have greatly benefited the so-called "poor" people, the working people in fact. But this word is a rank misnomer. The industrious workers of America are not poor; the poor people are the idle, vicious, dissolute, careless, and wasteful, and these always will be poor: but even these are greatly benefited by improved machinery."

——GATES AJAR: "Winifred, if I only supposed I *could* have some flowers in Heaven I should not be half so afraid to go."

"A happy home is the happiest thing in the world. I do not see why it should not be in any world."

——PUCK: "The summer boarder can take care of himself; if he can't, a great many landlords are laboring under a big mistake."

——"MAN charges the debit of his profit and loss account to Fate; but the credit he takes to himself. This is true in the moral as well as the material world."

——"CHICAGO lives in an atmosphere of meat. It is a part of the Ills. that flesh is air to."

Miscellaneous Advertising.

Hood's Sarsaparilla 100 Doses One Dollar

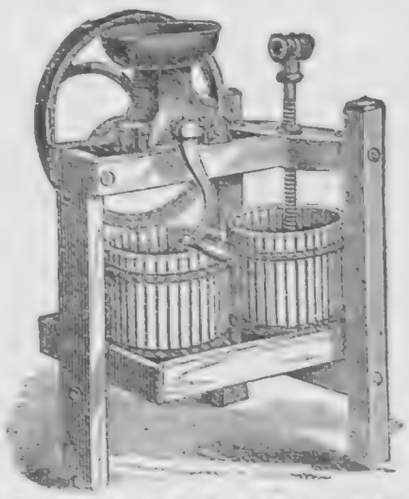
A Fair Trial of Hood's Sarsaparilla will convince any reasonable person that it does possess great medicinal merit. For all diseases of the blood, for dyspepsia, headache and nervousness, for that tired feeling or loss of appetite, it is reasonably certain to be of positive benefit.

JOHNSON'S ANODYNE LINIMENT ESTABLISHED 1810.

For Internal and External Use.

Stops Pain, Cramps, Inflammation in body or limb, like magic. Cures Croup, Asthma, Colds, Catarrh, Cholera Morbus, Diarrhœa, Rheumatism, Neuralgia, Lame-back, Stiff Joints and Strains. Full particulars free. Price 35 cts. post-paid. I. S. JOHNSON & CO., Boston, Mass.

NEW CIDER MACHINERY.



Send for new Illustrated List of Cider Machinery. Three new patterns and seven sizes, from small family size to large 8-barrel press. Please mention RURAL N.-Y. when writing.

HIGGANUM MANUFACTURING CORP., HIGGANUM, CONN.
WAREHOUSE: 38 So. Market Street, Boston, Mass.

SEED WHEAT

STRAWBERRY PLANTS, FRUIT TREES, SMALL FRUITS, DUTCH AND CHINESE FLOWERING BULBS, WINTER BLOOMING HOUSE PLANTS, FANCY POULTRY, PEKIN DUCKS, BRONZE TURKEYS, GERMAN HARES, &c. Our annual Fall catalogue, 1889, of Seed Wheat, Plants, Poultry, &c., will be ready by July 20. Samples of 7 new, hardy and productive varieties of Winter Wheat, including the ironclad RELIABLE and celebrated LEHIGH No. 6, will be sent with catalogue for 10c. in postage stamps. Address, SAMUEL WILSON, Mechanicsville, Bucks Co., Pa. Catalogues free on application.

THE RURAL NEW-YORKER,
No. 34 PARK ROW, New York.

SATURDAY, AUGUST 17, 1889

PROF. S. W. JOHNSON says that very finely ground bone is, at present, one of the cheapest sources of quickly available nitrogen and phosphoric acid. Remember this, you who use S. C. Rock, Cotton-seed meal, though the price is higher than last year, still remains the cheapest source of available nitrogen.

To dig or not to dig! That is the queston that is seriously agitating farmers who have discovered signs of rot in their potato fields. The first tendency would naturally be to take the potatoes out of the ground. But will they be better off in the air? The R. N.-Y. cannot assume the responsibility of giving anything more than a general answer. If the present fair weather continue, it will let its potatoes remain in the ground for a while at least. The R. N.-Y. will be very glad to hear from potato growers who have had experience with such seasons. Shall we dig early?

KEEP COOL! This is the R. N.-Y.'s advice to potato growers and farmers generally. It looks now as though some crops would turn out bad. Potatoes, apples, beans and some other products may prove disappointing. Keep cool. All is not lost. "It's a long lane that has no turning." In the long run farming, with careful attention to details, will pay. Some years prove unprofitable. There is no use in being discouraged. Every sort of business has its dark days, "To-morrow may be better." It is better to say that than to give up and settle into the belief that there is no hope ahead. Keep cool, friends. In any event, don't let your spirits, your temper or your courage catch the rot from the potatoes.

PROF. SANBORN discusses an important question on page 545. There are thousands of farms at the East where live stock must be kept. The farmers have always kept stock of some sort, and can not, even if they would like to do so, change to fertilizer farming yet. The trade in dressed beef has changed the whole aspect of affairs for these farmers. Beef making will not pay, dairying will not pay beyond a reasonable limit, and there is not a profitable market for all the forage that the farm produces. Therefore it is quite natural that farmers should want to investigate the profits of horse-breeding. The R. N.-Y. would like to hear from others on this subject. There is one thing we want to say about it—it never will pay to try to produce a flat-country horse on a hilly farm. The heavy, ponderous trucking breeds belong in level corn countries. There they obtain their best development. Lighter, more active animals are better suited to Eastern farming.

W. B. KEENEY & SONS, of Genesee County, New York, probably the largest handlers of beans in this country, write as follows concerning the prospects for the bean crop:—

"The bean crop last year paid quite well and arrangements were made this year to plant an unusually large amount, but the heavy rains that lasted through the most of June hindered planting, even after the land had been fitted two or three times. Crops on the Genesee River suffered more than those on higher land, and as they often yield one-third more per acre, the production will be very materially lessened in this section. Crops planted on dry land that received good care promised a large yield, but as haying and hoeing came together, beans in most cases were neglected. We cannot reasonably expect more than three-quarters of a common crop, and as many were planted about July 1, an early frost would make the crop still shorter.

The situation 'in a nut-shell' is this: With favorable weather in August and no early frost, we shall get three-fourths of an average crop. With unfavorable weather in August and an early September frost, the crop will not be one-fourth of an average."

BAD WEATHER FOR HAY.

THE hay crop is something immense this year. Ordinarily such a crop would mean low prices and a business stagnation, particularly when the fact is considered that a great surplus remained on hand from last year. But a great deal of this year's crop has been seriously damaged by the wet. President F. D. Douglass, of the Vermont Dairymen's Association, writes the R. N.-Y. as follows:

"I have over 50 acres of heavy grass now under water; while I have over 60 acres of small grain, which must be badly injured, with a continuance of such weather as we have had for some time past. There are probably 2,000 acres within 10 miles of my farm, on the same river, which would have averaged nearly two tons of hay per acre, and which are now in the same condition as my own low land. We have had a succession of floods, and there has been no opportunity for haying upon these meadows, a state of things never before known by the 'oldest inhabitant.' I have owned the farm on which I now live 23 years, and have never before had my hay crop injured by summer floods."

This is a fair sample of letters from many parts of the country. On low-ground, the hay crop has been quite seriously injured The R. N.-Y. judges therefore, that prices for the best quality of hay will continue firm.

CHEAPER TRANSPORTATION FROM THE FAR WEST TO FOREIGN MARKETS.

TO the States and Territories west of the Mississippi, the problem of cheap transportation to Europen markets is one of the most important. Their business is chiefly agricultural, and the principal products they have to send to market are therefore bulky. While they are farthest removed from foreign markets along the present lines of transportation, and have therefore to pay the heaviest freight rates, the prices for their products abroad control those for which they must dispose of them at home. It is very natural therefore that they should take a deep interest in any scheme looking to the establishment of shorter land routes to foreign markets. It is this consideration which for months has given special importance to the project of making, at the national expense, at some point on the Texas coast, a deep-water harbor to which should converge lines of railroad from different parts of all the southwestern States and Territories and from the rest of the western country as far north as Iowa and Dakota, and as far west as California. This subject has already been warmly discussed at several conventions in the West, and investigations have been made by government engineers with regard to the best place for a deep-water harbor on the Texas coast. Three points are now under consideration as the most eligible—Sabine, with a channel now about 10 feet deep at Sabine Pass, at the extreme eastern end of the State bordering on Louisiana; Galveston, about 50 miles further west, with a channel now 16 feet deep directly in front; and Corpus Christi in the western-central part of the State, with a channel at present about nine feet deep at Aransas Pass. The proposed harbor should have a depth of water to permit ocean steamers drawing at least 22 feet of water to cross the bar at any stage of the tide. Galveston appears to be the favorite place Not only is the water on the bar there much deeper than at any other Texas port, but of the 8,000 miles of railroad already constructed in Texas, nearly all have been built with reference to Galveston as the ocean outlet for the vast area of the State as well as for the States and Territories northwest of it.

An important convention is to be held at Topeka, Kansas, in October, to discuss the entire question, and to urge Congress at the extra session—which is now almost certain—to take prompt action in the matter. Delegates will be present from the States of Texas, Colorado, Nevada, Arkansas, Missouri, Kansas, Nebraska, Iowa and California, and from the Territories of New Mexico, Arizona, Utah, Wyoming and Dakota—which has only a Territorial vote as yet—as well as from the Indian Territory. Each State Committee is to be composed of five members, and each Territorial Committee of three. The argument in favor of such a harbor is strengthened by the prospect of a large South American trade which does not now exist, but which would grow up if Western produce had a cheap and ample outlet in the Gulf. A glance at the map of the United States will show that lines of railroad converging from the vast region west of the Mississippi to some port on the Texas coast, would afford shorter and therefore cheaper means of land transportation for goods in transit to Europe than a line to any part of the Atlantic coast, or to any other part of the Gulf, and a dollar saved in the freight of any product to market, ought to be at least 75 cents extra in the pocket of the producer.

OPENING OF THE GREAT SIOUX RESERVATION.

EVER since 1882 Congress has been legislating with regard to the opening for settlement of a part of the great Sioux Reservation in southwestern Dakota. This embraced an area of 22,000,000 acres, and the various tribes of the Sioux race inhabiting it, numbered about 45,000 of both sexes and all ages. As this vast tract, amounting to over 34,375 square miles, was over 1,000 square miles larger than the combined areas of New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut, the settlers in the adjoining States and Territories felt it an outrage that so large a body of fine agricultural land should be appropriated by so small a number of shiftless, unprogressive, idle Indians, who derived most of their support from the Government, especially since with the disappearance of the buffalo, a large area was no longer needed for hunting. This feeling steadily extended among all acquainted with the matter; hence the persistent and strenuous efforts to induce the Indians to sell their surplus area. The principal opponents of the measure have been the chiefs, whom the new order of things threatened with loss of influence and power as well as with great curtailment of their opportunities for self-enrichment. If half the land were sold to the United States, it was proposed that the remainder should be divided, in severalty, among the Indians, instead of being held in common according to immemorial custom. There would be amply sufficient to give a good farm not only to every family in all the tribes, but to every member, old and young, male and female. This would tend to make each family less dependent, and therefore diminish the power and influence of the chiefs. Moreover, the land having become private property, the chiefs could no longer use all they wanted of it for pasturing their exceptionally large herds of horses and cattle. Another class bitterly hostile to the proposed sale, has consisted of the "squaw men" or white men who, having married Indian wives, have settled permanently in the country and acquired much influence and a good deal of property, chiefly in cattle, horses and sheep. Under the new arrangement they also must lose much of their influence and many of their opportunities for accumulation.

There is no doubt also that a majority of the Indians, though willing enough to part with a portion of their territory for a liberal consideration, thought that by delay and haggling they could secure better terms than those hitherto offered. During the past few months, however, General Crook and the other Commissioners who have been urging the Indians to make the bargain, have strongly represented to them the probability that, in the event of their obstinate refusal, the government would either force them to accept the terms offered or take the land without payment, and that the chances for such an issue to the trouble had been greatly increased by the recent admission of North and South Dakota to the sisterhood of States, as their representatives in both Houses of Congress would be strong advocates of such a course. Having finally become convinced that they could not obtain better terms, and that they might be compelled to submit to worse, the recalcitrants yielded to the inevitable last Monday, and the Commissioners easily secured the requisite number of votes to effect the sale.

Hence the long-pending struggle is closed and 11,000,000 acres of fine farming land are ready to be thrown open to settlement as soon as the President shall issue a proclamation to that effect. As for the Indians, the interest on the $14,000,000 purchase money, will be added to their annuities, and the 11,000,000 acres still remaining to them, a region as large as the combined areas of Massachusetts and Vermont, are more than enough to give a comfortable farm to every family, and the opportunity is thrown open to them, under exceptionally favorable conditions, to demonstrate whether it is within the range of their capabilities to adapt themselves to the conditions and secure the benfits of civilization.

This settlement of the Indian problem is the most important event in the history of the Dakotas. The reservation formed a barrier between the eastern and western portions of the new State of South Dakota, thus shutting off direct eastern and western communication between the Missouri and the Black Hills, now regarded as one of the richest mining sections of the country. This barrier to progress is now removed. More important still is the fact that the 11,000,000 acres to be thrown open to settlement will afford good farms to 70,000 families, and judging from the settlement of Oklahoma, it will require vastly less than 70 days, perhaps less than 70 hours, to complete the settlement. For weeks, yea, for months, large crowds of immigrants have been encamped under canvas and in rude shanties on the eastern bank of the Missouri awaiting the settlement of the case, and thousands more have already started, or are about to start for this new Promised Land. The tract ceded extends from the Missouri River on the east to the Black Hills on the west, and from the White River on the south to the Cheyenne River, about the middle of the old reservation in the north: about 60 miles west from the Missouri, on the eastern line of Delano County, it stretches north as far as the Cannon Ball River, stretching about 50 miles to the west. It also includes a part of the rich Winnebago Crow Creek reservation on the east bank of the Missouri, south of Pierre. Three rivers and a large number of streams and creeks run through the tract, and the valleys are wonderfully fertile. The soil is reported to be for the most part a fertile dark loam, with a clay subsoil of the drift formation, which is said to be as rich as the loam of the surface and to be virtually inexhaustible. The country is well adapted for stock raising as well as for the growth of cereals. The climate is cold but dry in winter, and averages good, the mean annual temperature being 45 degrees above zero. The nights are cool and the days warm in summer. Three great railroads have already secured the right of way through the country, and will now be rapidly pushed to completion. The land will be reserved entirely for actual settlers, and will be a valuable addition to the agricultural resources of the nation.

BREVITIES.

Look out For a Varied Entertainment Next Week.

THERE seems to be no demand in the N. Y. market for sweet apples It seems more profitable to feed them to hogs.

COL. CURTIS writes about hotel swill for hogs on page 542. We shall have more to say about the disposition of this product.

THE R. N.-Y. has a photograph of the tools used on Mr. Terry's farm. We can easily count over 50. Farmers will like this picture.

SHEEP are handy animals for market-gardeners to have. They eat the vines of Lima Beans and peas and substances that other stock will refuse.

THE R. N.-Y. finds Breed's Universal Weeder an excellent tool. It will take the place of the cultivator among small plants, and as it is seven feet wide there is a great saving of time in its use.

DOES it pay to try to cure the stalks of early sweet corn? They do not cure readily and are too small anyway to amount to much as feed. We have been feeding ours green to the stock. The horses like them.

THE R. N.-Y. has never seen any chickens grow faster than the grade Dorkings. We like the Dorkings better than ever. Ours lay well, fatten readily and are handsome, intelligent, industrious, well-behaved birds generally.

"TAKE it one year with another," said a friend the other day, "an upland farm pays better than one on the low land." Is that so? Some of us have short memories. A season or so of drought might readily change this opinion.

COMMISSIONMEN are a little alarmed at the reports of potato rot. They are afraid of receiving large shipments of potatoes that will rot on their hands. Shipments of potatoes that are known to be rotting will result in loss and disappointment to all concerned.

THE wet season and consequent sticky condition of soils at all inclined to be heavy, will make the work of potato-diggers very unsatisfactory. Most of these machines are designed for shallow work anyway. It is quite safe to say that digging by machinery will not be fully satisfactory this year.

THREE valuable chickens on the R. N.-Y. Farm have broken their legs this year. As soon as discovered, they were taken into the house and treated. The leg was set—the bone being pulled into shape and a tight bandage of cloth bound around it. The chicken was then kept for a few days in a small basket. All those injured recovered and now show no signs of lameness. They liked the treatment so well that it is now hard to keep them out of the house.

Horseman.

HORSES *vs.* BEEF.

PROFESSOR J. W. SANBORN.

An important discussion; transportation charges on horses lower than on other domestic stock; advantages of Eastern over Western horses; greater care shown in horse raising in the East but less skill in breeding; horse-raising not a risky lottery; importance of good sires and dams; careless breeding common in the East; relative cost of raising horses and beeves; comparative consumption of food by both; experiments on this point; extra cost of horses, beyond the outlay for feed; expense of an extra year's maintenance; horse-raising conducted on sound principles a profitable industry.

THE following question is submitted to me for an answer: "It is proposed to encourage the breeding of horses on Eastern farms to take the place of the beef cattle that were grown there before the dressed-beef trade made the business generally unprofitable. Can it be done?"

The idea seems to be a capital one. Horses can not be transported in quarters without considerable cost for feed and attendance on the road. The horse presents, however, one great advantage to the Western grower that no other animal does—he brings more money per pound of weight than any other domestic animal, and hence less of his cost is absorbed in transportation charges. This is ordinarily a very important consideration in the production of any article at points distant from the markets for it. There are some offsetting conditions that are important. It appears to me that the New England horse is a hardier, livelier animal with more of what is termed life, and as the New Englanders call it, snap, than the Western horse. I do not know that the race-courses sustain this view. I presume that they do not. I do not know that their decision would be conclusive on this point. I am quite confident that we get more blind and maimed horses here than people get in New England.

Part of it is due to the greater care given the animals there. How much I do not know. It is hard to analyze conditions where they are so complex, without special study of them. I notice here a great amount of shoulder troubles which might be ascribed to the very cheap and poor collars used, and the more thoughtless laborers (colored labor is largely used in this State) and somewhat to the more inadequate protection from the weather, given the horses. I apprehend that this whole question of relative value of the horses of each section will be one of controversy. I incline to the view expressed.

One valuable advantage would accrue to the New England horse—it could receive on the smaller farms there, more attention and personal care in growth and training. The value of a horse, unlike that of other domestic animals, does not rest upon its pounds of weight, but upon other qualities. These qualities are various and cannot be discussed here. I may name the fact that a horse renders 10 to 15 years of service under ordinary conditions, and that $25, or $2 a year, for perfection of training and tractableness is simply nothing compared to the value in comfort and execution received. I have handled horses from large raisers and found that their awkwardness, due to inferior training was ineradicable.

More risks by injury are involved in horse than in cattle raising, but these may be accepted as only a small per cent. under good conditions, and when counted into the cost, they do not very materially affect the problem. The notion that horse-raising is a sort of lottery is a fallacy growing out of the vicious habits of breeding, which are worse in the East than in the West. A very large class of the farmers in New England raise colts only when they have a mare that is largely unfitted for service. Some lame, wind-broken, old, or otherwise unserviceable mare is bred in order to make some use of her. Breeding horses there, as a rule in farm life, is an incident, or a sort of accident, of the business of the average New England farmer. No study of the market-demands is made in a close way, and no such careful attention is bestowed on the matter as upon the breeding of sheep, cattle and pigs. Indeed I am of the opinion that the New England farmer breeds no domestic animal as well and thoughtfully as does his Western brother. This, if true, is explainable. I believe that the principle of breeding applied to the horse will result in the same certainty of success that it gives in breeding cattle, and that we can select our type and breed it, and secure sound horses right along by breeding from sound parents which are of sound ancestry. These suggestions seem to be necessary, as the process of breeding from all sorts of unsound and nondescript types has burdened New England horse breeding with unnecessary discouragement.

A survey of the inducements to horse breeding as compared to beef breeding shows an encouraging field. A 1,500-pound steer will bring, say, $75; while an 1,100-pound horse will bring $150, or the latter will bring nearly three times as much per pound as the former. Is there this difference in the cost of production? I most emphatically believe not, and that the horse is produced at a profit; moreover, a horse really well-bred—that is, bred from a good type of parents, sound and kind—is never below $150 in value, even in the hardest times.

The prevalent notion that horses eat more, per capita, than cattle is not true. It may be true that a vicious habit of feeding may convert the horse into a mere eating machine. The horse not having the advantage—or disadvantage, as it may be—of four stomachs and the opportunity to eat his breakfast over and to chew it finer, in consuming the same coarse hay that cattle do, necessarily chews it finer and hence much more slowly, and we misjudge the quantity consumed by the time of mastication. On this point we are not without testimony. The foreign trials that have come to hand show that the horse digests a little less hay than the ox; but to no very material degree; while the results may be said to be inconclusive on this point. Wolf, in making up his celebrated German feeding tables, allows for a horse at hard work, per 1,000 pounds of weight, 17 pounds of digestible food daily, and for the ox 16.1 pounds. Here is about five per cent. difference. But which does the more work? Really it requires no table of results to show us that a work horse utilizes its food for work as well as an ox. Do we not all know that a horse weighing 1,000 pounds, will plow more in a day than an ox weighing 1,500 pounds? And in almost any other work it will do more? If this be so, then the horse must utilize its food to as good an advantage as the ox, or to a better advantage so far as these facts can give evidence. The working horses on the college farm have consumed 23½ pounds of food daily, over one-half of which was in grain. A working ox consumes more. Indeed our growing steers weighing the same as these horses—1,100 pounds—consumed more per day.

It will be understood that the argument advanced by these data goes to show that horses make as good use of food as cattle do, forming a basis upon which to estimate the relative returns from horses and cattle. More direct testimony than the above is found in the experiments of Boussingault, of France, and Prof. E. W. Stewart, of New York State. Each of them fed colts by weight, and each of them found that as good a gain on a given amount of food was made by colts as by calves of equal weight. The average amount of food expressed in the equivalent of hay, required for the growth of a pound of colt after weaning, was 9.42 pounds, as found by Boussingault and Stewart. Experiments in cattle feeding mark this as a very good growth for calves of similar weight.

If it be true, then, that horse flesh costs no more than cattle flesh, or at most but little more, what reasons exist that make the horse cost more than the steer? Cost of service of stallion, care and training, and later maturity. Probably $25 will cover the first factors, while the last would mean extra maintenance fodder for one year. Now, as the average weight of a horse weighing 1,100 pounds (supposing, for convenience, we assume his birth-weight to be 100 pounds) from birth to mature weight, would be 600 pounds, we then have to supply extra maintenance rations for a 600-pound animal for one year, which at 1.8 per cent. of his live weight daily, would be 10 8 pounds daily for winter feed and a summer pasturing. This would give—hay being $12 per ton—$9.54 for hay and, say, $5 for pasturing.

The reader will understand that I calculate no grain in this extra year, and only a maintenance ration, because the amount it requires to make the growth above maintenance is the same whether we feed for two or four years, and I have set the amount required to make the growth against that required for the growth of an equal amount of steer. While I believe that the horse can be pushed to maturity as early as the steer, and that, so far as weight is concerned, that of this extra year need not be put on, yet we have to bear in mind that the horse is grown for his muscle and not for his fat, and that a flabby or immature horse is not in demand.

If we put our various sums together, we get $39 54 as the cost of a horse above the cost of a steer up to the present point. The interest and cost of the extra year's attendance (in New England the manure, is supposed to practically pay for attendance) and general or special risks of a horse over those of a steer—not absolute risks but risks more than we take on a steer—would probably make the sum over $50, so that the cost of a horse over that of a steer would be $50 on the basis of the same weight.

As the food direct costs no more for a pound of horse than for a pound of steer except as it is estimated in the $50 above, we have a 1,500 pound steer, at five cents a pound, costing $75 for food; while a 1,100-pound horse at five cents per pound, costs $55.00. If to this we add the $50 above, we get a total of $105, or to make the figures secure, say, in round numbers, $110 as the cost of the four-year-old horse.

In my opinion horse-raising entered upon thoughtfully and upon the right basis, will pay better than beef-making, and is worthy of the attention of that section of the country referred to in the question. It seems to me that a large proportion of the little and unsound horses now produced in the Eastern States are produced at a decided disadvantage.

Columbia, Mo.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

THE ART INTERCHANGE gives some very useful hints for summer fancy work. Especially pretty is a summer sofa pillow, made of heavy, soft, linen damask, well laundried to take off the gloss and stiffening. On this is stamped a large conventional design, such as horse-chestnut or oak leaves, or large-petaled flowers. The design should be outlined in white rope linen, the veins and midribs being done in the same. The open spaces between the parts of the design should be filled in with old gold rope silk darning. The surface stitches should be one-half inch long, the stitch taken into the goods less than one-quarter of an inch and the lines of the darning one-fourth of an inch apart. The darning is alternated, where one stitch is long, the stitch on the next line is taken midway the preceding one. This cushion is made up plainly, with at the corners cord and tassels of the rope linen, with some of the rope silk on the outside of the tassels.

* * *

AMONG other pillows described by the same authority are chair pillows of figured India silk. Occasional figures are worked with self-colored filo-floss, in long and short stitches, here and there outlined in gold. This cushion is bordered with a frill of cream lace.

Hammocks are made in the form of a round, cut-work design on brown linen, to be buttonholed in brown silk. The linen, when cut out, is placed over a round pillow of yellow Persian silk, puffed around the edges. The back is a plain piece of linen, also round, front and back being laced together, over the puff.

Dainty baby pillows are described, being worked with sprays of natural flowers in natural colors, bordered with a frill of the finest Torchon lace.

* * *

AMONG other books selected for our summer reading is the auto-biography of Harriet Martineau, the famous Englishwoman who wrote of political economy and social science. Her life is such a story of hard work and perseverance, under the discouragement of family trials, constant ill-health, and peculiarities of disposition, that one would imagine anyone would be the better for reading it. Naturally, she was inclined to worry—to look at the dark side, yet she says: "As I have grown older I have seen more and more the importance of dwelling on things honest, lovely, hopeful and bright, rather than on the darker and fouler passions and most mournful weaknesses of human nature." There, we should all be the better for living up to that.

* * *

THOUGH certainly an "advanced" woman, Miss Martineau had little sympathy with the extremists of "Women's Rights." She says that women, like men, can obtain whatever they show themselves fit for. Let them be educated—let their powers be cultivated to the extent for which the means are already provided, and all that is wanted or ought to be desired will follow as a matter of course. Whatever a woman proves herself to be able to do, society will be thankful to see her do—just as if she were a man. If she be scientific science will welcome her, as it has welcomed every woman so qualified. If capable of political thought and actions, women will obtain even that. The time has not come which certainly will come, when women who are practically concerned in political life will have a voice in making the laws which they have to obey; but every woman who can think and speak wisely, and bring up her children soundly, in regard to the rights and duties of society, is advancing the time when the interests of women will be represented as well as those of men."

* * *

SOME very pretty sofa pillows are simply covered with a rich material, preferably brocade, and then edged with a frill of soft silk.

* * *

"OVERDOORS," or railed shelves placed above the door, make very pretty decorations. They look like little balconies, holding china ornaments. They fit the top of the door, and are about six inches high.

LETTERS TO A COUSIN.

II.

DEAR COUSIN: You are a charming letter writer, for you always remember to answer my questions and to make some comment on what I've written you, which little attention I greatly appreciate. Some people never dream of answering a letter; they simply sit down and write of whatever is uppermost in their minds without ever giving a thought to the letter which they have received. Their letters may be interesting and entertaining, but the writers are not, strictly speaking, good correspondents. You know the old saying that "the life of a jest lies in the ears of the hearer" and if the hearer does not make a bright reply or "acknowledge the corn" one might as well never say good things. I am delighted when you write to me about people and books and tell me in your frank, bright way, how they have impressed you: then if I meet the people or read the books you have described I am doubly interested. You say that "People I've Smiled With," by Marshall P. Wilder, is an entertaining book. I read a review of it, with a sufficient number of quotations to give me a pretty good idea of the style and general tenor of the volume. The author seems to be a great admirer of Mr. Blaine and appears to consider him a genial, kind-hearted man, charming companion and a good story-teller.

Some of Mr. Wilder's remarks are very original. I don't think I ever before heard of the east wind going through one "like a piece of bad news;" but isn't the phrase wonderfully expressive? The east wind and bad news are certainly two of the most disagreeable elements we mortals have to encounter on our terrestrial journey. Of the two, however, I believe the east wind is the more depressing on the spirits.

[Isn't the talk about the cheerless, depressing and insalubrious effects of the east wind in this country a mere repetition of the talk about the effects of the east wind in Western Europe? The conditions are exactly the reverse in both hemispheres, however. In the Old World the east wind in summer is dry and hot, having swept over the solid land from the Pacific. In winter it is cold, piercing and dangerous to health after its passage across the snow-clad surface of two continents. On the other hand, the west wind is always mild, rather moist and salubrious, tempering alike the heat of summer and the cold of winter with the more even temperature brought from the broad Atlantic. Now, the conditions here are the reverse. The west and especially the northwest wind sweeping from the Pacific across the continent, is robbed of its moisture in summer and of its heat in winter, and is dry in one season and cold in the other, and at all times less salubrious than the east wind which brings the purer, more temperate and moister air from the ocean. Books written by Europeans very justly dwell on the misery of the east wind, and the talk is often inconsiderately repeated in this country where the conditions are entirely different. The character and effects of any wind do not depend on its direction, but on the nature of the country and climate from which it comes.—ED.]

Some one told me not long ago never to ask a favor of any one on a rainy day or on the 5th of July, the reaction after the Glorious Fourth usually making business men desperately uncivil. It is said that he who watches the clouds never accomplishes anything, but that is, in a measure, untrue. It is well to make hay on a fine day, and it is best to approach a person from whom you want a favor when you feel tolerably certain that he or she is in a good humor. After the dinner hour is a good time, but never, never before breakfast. "Strategy, my boy, strategy," as the old man said, will sometimes achieve success where plain, straight-forward action would fail.

But stratagem is utterly foreign to some natures. I don't suppose that you, dear,

"ever beat around the bush" for anything in your life, and if you should try, I fancy you would get hopelessly entangled. Do you remember the elaborate plans "Huck Finn" and "Tom Sawyer" made when they set out to "steal the nigger?" How, instead of simply getting away with him, they schemed for weeks, sent anonymous letters and had the whole neighborhood in a blaze of excitement, before the eventful night for their deed arrived. I heard Mark Twain himself read that part of "Huckleberry Finn" last winter, in his irresistibly funny manner. Oh, how he would sing-s-o-n-g out his words! I think he possesses the proverbial Yankee drawl in an absolutely perfect state of preservation. If I mention Mark Twain once or twice after you are certain you have heard all you care to hear about him, just let me know and I will *try* to write a letter without mentioning his name; but I won't make any promises, for I like him very much indeed, and his droll remarks are continually recurring to me, so that I may offend again and again.

By the way, was there ever any one so easily offended as our friend D—she is the most "touchy" creature I ever knew, always fancying some one is slighting her or making insinuating remarks for her benefit, when in reality no one is farther from the suspected person's thoughts than herself. To be easily offended is to make a great goose of oneself on a thousand and one occasions. If we would only think more about pleasing other people and saying nice things to them, we would not have so much time to ponder over our own grievances. If anyone were to say something to me with the obvious intention of hurting my feelings, I think I would try my level best not to let him have the satisfaction of knowing if he had accomplished his purpose. You never knew—did you?—that I could sermonize even a little bit? I humbly acknowledge that it is not my forte, and ask your pardon for having thrust my opinions upon you. A big blank sheet of paper sometimes tempts one to say more than one would say if talking face to face with another in immediate danger of being drawn into an argument in which one might come out worsted.

If you disagree with me on paper, I can take ample time to reply; but in conversation everything depends on being bright and prompt—hesitate, and you are lost. Ah, if we could always think to say the right thing in the right place, we would be spared many a regret. I read the other day of an old gentleman of 80, who still remembers with the keenest remorse a conversation 30 years ago, in which he might have made a witty epigram had he thought of it immediately, instead of just five minutes too late; and he will repeat the conversation word for word and show how aptly his remark would have come in. He must be an exceedingly vain old fellow; don't you think so? He ought to have gone home and written a book for the express purpose of introducing his brilliant jest, surely it deserved an elaborate setting if it was worthy of being remembered 30 years!

I believe I have thought of the right thing to say to you just now, and without having fatigued my brain to any great extent either. I would like to have you visit me. Do, please, come. You know the attractions of the place—they are the same now as they were ten years ago; the air and the water and the lake breezes are ever the same.

Affectionately your Cousin,
DOCIA DYKENS.

SHALL WE SEND OUR DAUGHTERS TO BOARDING-SCHOOLS?

THE day is past when any question as to the propriety of educating girls can arise among sensible people. "Give your girls all the education they will take,—strong, solid, informing education,"—is the language of the vast majority of the faithful advisers of this generation. But shall we have our girls taught at home by governesses? Shall they attend day schools, still preserving their home-life intact? Or shall they be sent away from home to study in boarding-schools and colleges for a year or more before their education is completed?

A boarding school conducted by a wise, just, refined man or woman is undoubtedly a good place for anybody old enough to leave home at all,—let us say 16 years old or more. A bad boarding-school is worse than a bad home,—which is very nearly the worst thing on earth. Only the good boarding-schools and colleges, of which there are now a goodly number in existence, are considered in this article.

We are apt to pet our girls too much. Petting outside of judicious limits, is good for neither plants, brute-beasts nor the human animal. Our girls must be taught, in these days of sudden and awful changes, to rely upon themselves; and while retaining the sweetness and modesty of true womanhood, they must be given as much of independence and of strength as we can instill into them. A girl will get these qualities far better in a good boarding-school than she can acquire them at home. Loving mothers are apt to do too much for their daughters. A girl at school has to do things for herself,—to see that, as old George Herbert quaintly says:

"God gave the soul brave wings. Put not those feathers
Into a bed to sleep out all ill weathers."

Thus she often learns to appreciate her mother's work for her—a most valuable lesson. 'Absence," too, "makes her heart grow fonder." She comes to love her home more, and "short retirement urges sweet return."

At a boarding-school, a girl comes to know other girls, often from widely separated sections of the country. Thus her ideas of manners, customs and types of character are broadened, as by travel. This, alone, is often worth the price of a year's stay at the school.

It is true also that at boarding-school, little mannerisms and disagreeble ways, unnoticed perhaps, at home, are thrown out into bold relief, and wise instructors take measures at once to remove or to modify them. "The toning-down" and "polishing-up" which a girl often gets at a good boarding-school may transform in a single year, a restless, hawking, nail-biting, stoop-shouldered hoyden, into a quiet, erect young lady.

Again, the friendships of boarding-school and college life are usually among the choicest possessions of one's prime, and are stronger than they could have become under other circumstances. Young, ardent, loving souls meet and are welded together as they never can be in later years. The love and friendship for noble teachers, too, seldom formed elsewhere as in boarding-schools, form, often, a saving influence in a girl's life.

There is nothing which brings young people to their level like sending them away to school. Thackeray refers to that "over-bearing sense of their own importance which stay-at-home people commonly learn." Even in a small boarding-school, a spoilt and selfish girl quickly observes that the earth has ceased to revolve around her as it did at home. It is a hard but a wholesome lesson.

The regular and punctual habits acquired during a year or more in a good boarding-school, are invaluable to our usually unsystematic girls. The catering of a judicious steward, under the direction of a competent faculty, is, also, much more likely to be good for youthful stomachs than the mixed diet common in too many homes. One of the most cheering signs of the times is the intelligent attention paid to diet, exercise and general health, in our boarding-schools and colleges for young women.

It is true that

"Nothing loveller can be found
In woman, than to study household good,
And good works in her husband to promote."

But in these days of complicated *menages*, a woman must be strong and keen-sighted, who attains to the true good of her household. In order to rightly train up little children, alone, she should have the wisdom of Solomon himself. No great race can be evolved by educating the fathers alone, children are the inheritors of their mother's qualities equally with their father's. There is no danger that our women will not be loving and devoted enough. Let us do all we can to make them self-reliant, reasonable, clear-headed, strong.

"All success
Proves partial failure; all advance implies
What's left behind; all triumph, something crushed
At the chariot wheels."

But with all the dangers and disadvantages,—and they are not few or insignificant,—which attend upon the sending of our girls away from home to obtain a share of their education, it would seem to be better, on the whole, that they should go.

Kate Upson Clark, in Ladies' Home Journal.

GOLDEN GRAINS.

AN exchange says everything has its use if utilized in the right way. If "sitters" could be brought to hold their convocations at the greenhouse, the tobacco smoke would destroy the insects and the scurvy stories would doubtless prove a valuable fertilizer...

TALMAGE says God does not come to the heart as we set a cask at the corner of the house to catch the rain in the shower. It is a pulley fastened to the throne of God, which we pull, bringing the blessing.....

THE haunts of happiness are varied, and rather unaccountable, but I have more often seen it among little children, and home firesides, and in country-houses than anywhere else says the Rev. Sidney Smith.....

THE INDEPENDENT reminds its readers that if every Christian were to try to secure the conversion of at least one person every year, the annual additions to the churches would be millions instead of thousands.....

ONE who can get a true sense of the proportion of things has a large part of true manliness. To know that small things are small, and that it is not worth while to bother about them; that large things are large, and that one must give his heart to them, this is common sense, and this is Christian. Dr. Crosby calls men who waste their lives in trifles "strutting Tom Thumbs, who would be majestic, but only excite smiles."....

IN Mr. Moody's talk about the Bible he said: "Take, read and feed on the whole Word of God. Don't throw this and that passage in the book aside. If you can't explain, can't understand it, don't try; don't worry because of it. There are depths in it no one, however acute his theology, can sound."....

THE INDEPENDENT adds editorially, it is the simple, solid Gospel truths that lie on the face of the Bible that will do us good. Some people are not satisfied with the gold in the mine, and so they think to improve it by "salting the mine," putting things into it that were never there, so as to have the satisfaction of digging them out again. This is not legitimate Bible study.....

Domestic Economy

CONDUCTED BY MRS. AGNES E. M. CARMAN.

Hating, sneering at others, despising others, holding yourself above them DON'T PAY. *You may hold yourself up ever and ever so high. People look at you and smile at or pity you, and the first thing you know God knocks out your underpinning and down you come and there is scarcely one to shed a genuine tear. Hate not at all. We can't afford it. Love all you can, for it is love that makes this world beautiful. Love is the basis of happiness. It is God's right bower.*

EXTRACTS FROM SUNDAY-EVENING TALKS AT THE RURAL GROUNDS.

WE can all sympathize with the old Dutchman who said that the only trouble with his life had been that his front sight was not equal to his hind sight. What he meant was that he could do excellent work, never make a mistake in fact, if he could only have the advantage of experience without being obliged to pay the usual price for it. So could we all for that matter. If we could go back in life 10 years with a careful record of all the failures and successes we have gone through no doubt, if we were honest and ambitious, we could make a much better life record than we have made. I can see plenty of instances in my own life, where a sure intimation of the course events were bound to take would have saved me a load of worry and work. With hot-headed enthusiasm I have plunged into enterprises that resulted in nothing but disappointment and loss of energy and time. In many instances I would not listen to the advice of those who could see the end. The only thing that could have stopped me would be the hard and bitter experience that could not be obtained in any way except by working it out. The enthusiasm, the making light of obstacles, the overconfidence, made up the front sight. The disappointment, the empty pocket-book, loss of time and energy make up the "hind sight."

So we find it all through life. There is always this inability to transpose these two "sights." And the point I want to consider to-night is whether this arrangement is not, after all, as just as we are deserving of? One of the fundamental laws of what we term Nature, that wonderfully incomprehensible power that seems to control and direct all life, is that nothing that lays claim to energy and growth can jump abruptly from one stage to another. There must be a gradual development, a steady growing on well-defined principles, an almost unconscious adding to from hour to hour and from day to day, before solid strength or permanency of design can be found. It is so with the building up of physical strength; it is so with the building up of character.

What spirited young man of 20 does not feel sure that he can carry out all the duties of his 50-year-old employer? How indignant he is at an intimation that every one of the 30 years that separate them must be carefully and earnestly studied out before he can hope to fill out every detail of the old man's place. Put the younger man into the older man's place and in nine cases out of 10 he would make a most ridiculous failure. In the one case where he might succeed in a business way, he would ruin his health or his disposition. It will be simply a case of trying to cut across lots through the mud. You can't possibly take a sudden jump into a place that you have not fairly and honestly worked up to, and hide your trail any more than you can hide the prints of your boots in the mud.

It seems to me that a thorough understanding of this vital principle would save much of the complaining about a defective front sight. A great proportion of the foolish enterprises that we take up, the losing games that we begin, have for their opening chapter this insane belief that somehow we can be first among all the billions of people that have lived since the world began, to break this solid rule of life. If we would only understand that we absolutely cannot hasten our natural development of strength or character or wisdom we might be saved many an hour of trouble and many a moment of desperation. And yet, in spite of all the disappointments, is it not a wise provision of this masterful Nature that separates the fore sight from the hind sight and absolutely compels us to work out the latter by the exercise of our own judgment and energy? Show me one who never was forced to do self-thinking, who always had the plans of others for guidance, who never thought over and profited by a mistake, who never paid out of his own life the price demanded for personal experience, and I will show you a weak, careless, selfish character without a single knob on which to hang true friendship, or a single hole into which true sympathy may creep and find a welcome. I do not think God ever intended that man or woman should go through life without making a single mistake. If He had, He would surely have made the two "sights" we have been talking about equal; for until they are made equal we shall all go on working away at plans that must carry some element of regret. I rather think He intended these mistakes and errors of judgment as an important and necessary part of life. They are educators, strengtheners, refiners, even comforters if we will only use them as such. I do not believe there is a single waste product in Nature. Every rule of life has its use if we will but hunt it out.

The wise man tries to fit the hind sight of one experience to the front sight of another. Success in life depends to a great extent upon physical capacity. A deep, logical mind, a brilliancy of originality, an unnatural keenness or comprehension seem to be the most powerful elements of success, but they are, every one, regulated by physical condition, the circulation of the blood, the digestion, the state of the nervous system. Say what you will, the great things of the world have been wrought out by well ordered stomachs rather than by supernatural brains. How much can I stand? What is the limit of my endurance? These are questions of absolutely vital importance. They should be made a part of every "front sight." We must go to experience for the hind sight that is to accompany them. We know that certain foods do not agree with us; we know that we take cold when we expose ourselves to certain conditions, we know that there are certain bodily signs, headaches and tired feelings that indicate some mistake in living. The "hind sight" teaches us to stop at this sign and apply the proper remedy. There seems to be a general belief that to each one is given some supreme chance, the germ of some great opportunity. If this chance be grasped and pushed to its fullest extent, success follows. Let it be neglected and the chance of a lifetime departs never to return. I have never believed in this idea though I know that with nine-tenths of my friends it amounts almost to a superstition.

Let a man or woman become convinced that his or her great chance has departed and they grow into discouraged cynics, living but to blame themselves for their supposed misfortunes. From the moment that they become satisfied that the one possible prize reserved for them has been lost, the slow and sure development that alone can make one capable of doing great deeds, thinking great thoughts or living truly noble lives is stunted. I do not believe in this one prize doctrine. Most of us start in life with a fair chance. It is true

Miscellaneous Advertising.

When Baby was sick, we gave her Castoria.
When she was a Child, she cried for Castoria.
When she became Miss, she clung to Castoria.
When she had Children, she gave them Castoria

that those who succeed best are generally those who have the best knack of adaptability, who can condense their exertions, who seem to know by instinct when this condensation will give best returns, but no living person has any moral right to argue himself into the belief that his chances have all passed him or that the mistakes of his life—the hind sight may not be made as valuable to him as though his life had been one round of successes. Here is a totally deaf man making an honest living; here is a blind man supporting a family in good circumstances; here is a man without arms earning his own bread—all of them cheerful, hopeful and full of that thankful philosophy that bubbles up from every misfortune and every mistake. What a lesson such people teach to the thousands of able-bodied folks who sit down and fold their hands in sorrow because they did not know enough to take advantage of their "one chance" or because they cannot live their lives over again and thus do certain things differently. And another thing—why do we always refer to a "success" in life as viewed from a worldly point of view? This man becomes a great banker, this one manages vast railroad enterprises, this is a mighty soldier, that one is the best farmer in the country—they all proved "successful." Here we have a boy who started out in life hopeful of becoming a banker, a railroad prince or a great soldier, but who became only a poor cobbler. The world never heard of him. He could not even do superior work at cobbling. But he helped the poor and the needy, he comforted and he blessed. But he did not "succeed" as we view success. But how did God regard his life? Most of us start wrong. We must be rich, we must be great, we must have easy lives, we must be able to command as much attention as our neighbors do. And the more we strive the more are these desires intensified—the greater the disappointment when we fail, and the greater our inability to substitute the gain of our experience for what we imagine is our loss.

If life were all open before us, if we knew just exactly what to do; if there were no mystery about it all, I believe there would be no stimulants to physical or mental exertion; such a personage as the self-made man would be impossible and we would all become puppets walking listlessly through our little lives to the end. I am glad that there is a mystery about it. I do not care particularly to solve it. My "hind sight" or the portion of my life that I have already lived, seems to have taught me several rules of life that are unvarying.

Work.—There is absolutely nothing accomplished without it. The results we gain in any department of life simply represent work—good or bad, careful or careless. Nothing can ever be accomplished without work; poor work will ruin any reputation 10 times as fast as good work will build it up again.

Health.—Everything is possible with it, nothing is possible without it. Each one is given a certain degree of health. As that health is guarded and nourished, the work of that person becomes strong or weak.

Competition.—There are dozens of people starting out for every desirable place. But one can hold it. Why is he chosen? In nine cases out of 10 it is because he concentrated every energy of mind and body to the task of mastering the duties involved in that position. His temper, his ways of thinking, his ways of living were all picked over and rearranged to fit into that groove. The very successful person is a specialist. No one who spends life in jumping from one trade to another can ever master one. There always will be competition. The bright, original, keen mind welcomes it, because it presents a chance for a clearer distinction between the good and the poor.

Happiness any person can obtain, the poor and the rich, the sick and the well. A good digestion, a clear conscience and a regular employment will bring it. "How much fun can I have out of life?" I wish more men and women would keep asking themselves this question. I do not mean that life should be given up to a search for fun, but I would have more people look on the "bright side" and hunt more for the laughable side of life generally. I have the most abundant faith that if one will continue to work earnestly and studiously, concentrating his work, content to develop in the natural way, cultivating health and good nature to the best of his ability, his place in the world will be assured even if his slow and steady course should pass by the one 'supreme chance." I have made mistakes—who has not? Why should I grieve over them now and long for the impossible—a chance to try and see if I could not dodge them the second time? I shall try to not make them again. I shall take what lessons I can from them and go on to meet whatever the future has in store, and I like to believe that somewhere, some time I may get a chance in life where the conditions are such that these two sights may be even.

HOUSEHOLD SAYINGS.

IN the preface to the "Professor at the Breakfast Table," Dr. Holmes says: "How a stray sentence, a popular saying, the maxim of some wise man, a line accidentally fallen upon and remembered, will sometimes help one when he is all ready to be vexed or indignant." He might have added, "When he is ready to be discouraged, fretful, careless, or guilty of a dozen other failings [to] which man is prone." Every household has its own sayings, and a few belonging to one family circle are given below.

* * *

WHEN we know of a whole family made uncomfortable by the treatment the wife and mother gives her husband and children; or of the commotion one interfering woman can make in a church, a family, or a neighborhood, we pass to each other the household phrase, "One woman's influence!" We often forget, though, to say it when we see happy children and social circles brightened by a good and gracious woman.

* * *

WHEN the day begins late and the work goes cross-wise, the ironing interferes with the cooking, and the churning comes in the heat of the day, we exclaim: "It's no use to chase the hour we lost this morning; it grows into three before we catch it," and truly the work gets so tangled that it all takes more than the usual time, and the fretting it causes does not hasten it any.

* * *

BUT when an early start sets all the household machinery running smoothly, so that the dishes are washed and the churning is done while the day is cool, and the ironing is going on at the same time, so that it is out of the way when the "big pot" and the "little pot" must go on for the vegetable dinner, we smile with pleasure and say: "We have time by the forelock to-day." To-morrow's work will go smoother, and the canning may be done then.

* * *

MONDAY morning friends come to stay to dinner, and we plan for a full week saying: "Company to-day, we may look for them all the week," and Saturday night we tell the visitor who has come last, that he or she was expected; for our cousins, uncles, aunts and friends have made the whole week a holiday by their visits. When the saying fails to turn out true, of course we forget it, and so preserve it and our full faith in it.

* * *

ACCIDENTS never daunt us though numerous enough at times. After the first scare, on being assured no serious harm has been done, some one says: "We need not fear, it is our family luck to escape where others would break their necks." The baby falls into the cistern, but is rescued uninjured; the horse runs away, scatters the sleigh along a mile of road, but the girl-driver rolls out when the back falls off, and in an hour can laugh with the rest over the fright. But "luck" is a poor dependence, and we close the cistern and let the men drive the runaway horse in spite of the family charm.

* * *

WHEN the children build air castles, laying the foundation of each one by saying: "When we are rich," mother says: "Wealth and our family will always be strangers; you never heard of any riches in our family, did you?" And father quotes from the prayer of Agur: "Give me neither poverty nor riches," and yet we build our air castles hopefully, though perhaps less extravagantly, and often think there is better wealth than that represented by dollars and cents.

* * *

IF study seems difficult, or plans fail after hard work to make succeed, Holland's lines are ready from the household sayings: "All common good has common price, exceeding good exceeding," and the greater the prize we are working for, the higher we feel must be the price we pay in care, time, thought and work, and in that difficult coin to command—patient perseverance.

* *

AN admonition that is sometimes very irritating when misapplied, is a comfort when long days of work seem to stretch out endlessly down the future, and there is no promise of long, lazy vacations, full of the delights of eating without cooking, and of enjoyable cool, spotless rooms without touching broom or dust-cloth to make them so. When the weeks are full from Saturday to Saturday again, and the work is bringing some cherished end nearer, if not a vacation, we say with pleasure:

"Rest is not quitting the busy career,
Rest is the fitting of self for one's sphere."

* * *

ANOTHER stanza is helpful for some circumstances, and we apply it in various ways to our occupations. It begins:

"Labor is life, 'tis the still water faileth,
Idleness ever despaireth, bewaileth:
Keep the watch wound, or the dark rust assaileth."

"Now look at these tins, if they had been in use this damp weather they would not be rusty;" we say; or, "Use this table-cloth this week; it has lain here until it is getting yellow. It must have its turn on the table oftener." Then some one quotes our lines and we wonder what faculties we are letting lie idle to rust, or yellow with time. A. B.

A SUBSTITUTE FOR A REFRIGERATOR.

THE scarcity of ice has compelled us to adopt various methods of preserving meats, milk, etc. We tried placing them upon the cellar bottom and covering them with tin pans, screens, etc., but all such devices were incomplete and unhandy. We finally devised a box about five feet long, three feet wide and deep enough to hold a milk pitcher. For convenience we divided it into two compartments by placing a partition in the center. Over the top we placed two lids or doors covered with ordinary wire mosquito-netting, each fastened to the box with hinges, with a knob for lifting it. We placed this box on the cellar bottom, and it answers the purpose of a refrigerator admirably. In fact, we think things keep better in it than they do in an ordinary ice-box. The whole thing can be made from an old dry-goods box or some waste lumber and a couple of yards of mosquito-netting with a couple of hinges and knobs. J. H. G.

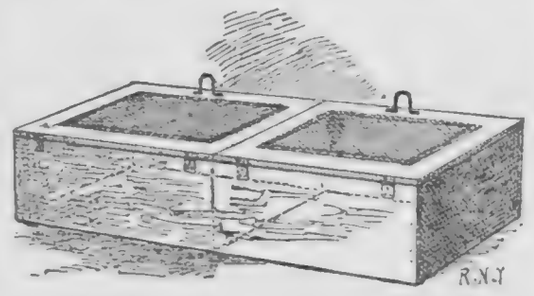

Fig. 207.

When You Know

That scores of people have been cured of Boils, Carbuncles, and Scrofulous Sores by the use of

Ayer's Sarsaparilla

why not try it yourself? As a blood-purifier, this medicine has no equal. Listen to good advice: Take Ayer's Sarsaparilla, and no other.

"I had numbers of carbuncles on my neck and back, with swellings in my armpits, and was tormented with pain almost beyond endurance. All means of relief to which I resorted failed until I began to use Ayer's Sarsaparilla. One bottle of this remedy restored me to health."—S. Carter, Nashville, Tennessee.

Ayer's Sarsaparilla,

Prepared by Dr. J. C. Ayer & Co., Lowell, Mass.
Price $1; six, $5. Worth $5 a bottle.

W. R. & CO'S IMPROVED BUTTER COLOR

IF YOU REALLY WISH to use the very best Butter Color ever made; one that never turns rancid, always gives a bright, natural color, and will not color the buttermilk, ask for *Wells, Richardson & Co's*, and take no other. Sold everywhere. More of it Used than of all other makes combined. Send for our valuable circulars. WELLS, RICHARDSON & Co., Burlington, Vt.

News of the Week.

HOME NEWS.

SATURDAY, August 10, 1889.

AN Ice Trust at Indianapolis from the opening of the season till the end of last week kept the price of ice at 140 per cent. more than was charged last year, regardless of public protest and indignation. A week ago it attempted to put the price higher; but one dealer refused to agree to this and withdrew from the compact, having previously purchased enough lake ice to supply the whole city. He at once reduced the price 50 per cent. and now there's a desperate cutting of rates among the extortioners. *Sic semper tyrannis!*..... Claus Spreckels has given orders to duplicate his mammoth sugar refinery at Philadelphia at once. When this is done the producing capacity of the works will be about 4,000,000 pounds of sugar per day, and the entire cost of the plant between $4,000,000 and $5,000 000. The present factory will be ready for business September 15. Claus doesn't belong to the Sugar Trust, but he keeps even pace with it in putting up prices.. .....There's a movement on foot to create a Cotton Trust or Syndicate to control all the cotton mills in New England, if not in the entire country. It is stated that the amount of money already subscribed, chiefly in England, is enough to buy the cotton industry of America. The Fall River mills alone have a capital of over $20,000,000 and an investment of upwards of $30.000,000 more, owned by thousands of stockholders, who wouldn't sell for anything like prevailing prices. The present ticklish condition of European politics and the danger of a continental conflagration at any hour are inducing capitalists and all others who have money to invest, not only in the United Kingdom, but also in Germany and most of the continent of Europe, to seek for investments in this country. In the event of war all investments of hostile aliens in any country are liable to confiscation and are certain to meet with enormous depreciation in the most favorable event, hence the anxiety to make investments in this country with which there is really little chance of any European country going to war. Of course the greater the amount of capital invested here by the citizens of any foreign nation, the greater would be the pressure they would exercise on their government to prevent it from going to war in case of any embroglio with this country..... Latest advices from Graytown, Nicaragua, the Atlantic port of the projected canal, say the actual work will be under way by Jan. 1. All preparations are being now rapidly pushed forward. The "terrible example" of the Panama fiasco will be a lesson to the American Company in this strictly American enterprise. The men will be well boarded and housed and get all goods at first cost, every precaution being taken to avoid the dissipation, drunkenness, starvation, mismanagement and death that caused the collapse of De Lessep's grand scheme. Work will be pushed simultaneously from the Atlantic and Pacific coasts and it is expected that the canal will be completed in 1894 or 1895 .....The great Chesapeake and Ohio canal, the originator and first president of which was George Washington, and which was completed from Georgetown, D. C., to Cumberland, Md. in 1850, was greatly injured by the late floods at the time of the destruction of Johnstown, Pa. It had long suffered as a prize of the machine politics of Maryland, in which its whole length stretches along the Potomac. In all about $40,000,000 have been sunk in it, and now it is in danger of going into a receiver's hands, as capitalists refuse to subscribe the $300,000 needed to repair the recent damages, unless the present managers are removed and the work is entirely taken out of politics .... The 30th anniversary of the striking of oil in Pennsylvania, will occur on August 29..... A treaty of peace, or it may be only a truce, has been patched up between the leaders of the Knights of Labor, the Federation of Labor, and the Brotherhood of Railroad Firemen and Switchmen, as the programme says: "in order to disabuse the minds of our fellow-toilers of the false impression that any rivalry prevails among the various orders." Having the same object, all should certainly heartily co-operate in achieving it; but it's quite likely that the leaders will go on poaching on one another's preserves as of old.....Hippolyte has been again three times repulsed from Port au Prince in Hayti. He managed to capture 18 prisoners, however. Some of them were shot in fun, and the others after their arrival in the dusky chief's camp, had their throats cut in sight of the whole body of troops, who went into fantastic ecstasies at the sight. In savage reprisal Legitime ordered his prisoners—eight in all—to be taken to the market place where their throats were cut before the populace, who yelled themselves hoarse as each quivering victim fell. The first few were gagged; but the gags of the others were removed in order to add to the exultation of the frenzied mob by the agonized shrieks of the butchered prisoners. Civilized nations are combined to put an end to the horrors of African barbarism in the Dark Continent; why shouldn't they promptly combine to put an end to the horrors of African barbarism in the West Indies?..... ..... An election for State Treasurer and members of the legislature was held the other day in Kentucky. Of course, the Democrats carried the State, by about 40,000 majority. The Republicans are reported, however, to have made some gains in the legislature. The Prohibition vote was, of course, very light..... Martin Burke, the Cronin suspect, arrived in Chicago from Winnipeg, Tuesday. On the road he was heavily manacled and strongly guarded. The police expect he'll turn informer so as to save his own neck by putting those of his confederates in nooses. The world would be well rid of the entire crew..... The Gentiles are jubilant at their victory in the local elections at Salt Lake City, Tuesday, and will turn the present Mormon rascals out next February.....

Monday, elections in the Cherokee Nation were favorable to Chief Mayes's faction, indicating the defeat of the proposition to sell the Cherokee Strip... .....The wrangle still resounds between Postmaster-General Wanamaker and President Green, of the W. U. Telegraph Company, about the compensation to be allowed by the government for telegraphic service. The P.-M.-G. insists that the telegraph companies have received valuable concessions from the nation; Pres. Green declares that the Western Union never received "a stone, a stick of timber or a foot of land under grant of Congress." The Pacific Telegraph Line, however, from the Missouri River to the Pacific, a distance of 1,800 miles, was built upon a government subsidy of $40 000 a year for 10 years, while its net cost to the projectors was only $30,000. It was gobbled up by the W. U. cormorant and capitalized at $6,000,000! On this immense mass of "water" the dear public have been paying a heavy interest. Many of the other lines raked in by the monopoly got as generous an allowance of governmental pap..... Some time ago the New York City authorities, in compliance with a new law, ordered the various telegraph companies to remove their wires and poles from certain streets on which conduits had been laid under ground for the reception of the wires. Most of them obstinately refused to do so, the Western Union, by far the worst offender, being also the worst kicker. Mayor Grant ordered the work to be done at the city's expense. It cost $45 000, while the old poles, wires, etc., have just been sold at auction for $1,500. Jay Gould and his *confréres* are therefore $43.500 ahead..... .....There have been a number of disastrous cloud-bursts in various parts of the country during the week. They appear to be useful down in Georgia where they are called "trash-movers."..... Last Wednesday on a two-mile circular track, at Laurel, Md., a three-ton electric motor made two miles a minute for 10 consecutive minutes. The new system of transportation is intended for express packages, mail matter, newspapers, etc., and is to be pushed rapidly into public use. Edison calls it "the greatest conception since the telegraph"..... In the Connellsville region, Pa., every one of the 776 coke plants and over 14,000 coke ovens are idle on account of one of the worst strikes ever known in that scene of chronic strikes. The strikers are ferociously turbulent against incoming scabs, many of whom have been bludgeoned and maimed and a few shot.... .. Last Sunday night Spokane Falls, a growing town of about 20,000 inhabitants, in the midst of a rich agricultural country in east central Washington Territory, followed the recent example of Seattle on about the same parallel in the western part of the Territory, and for the most part went up in flames and smoke. Thirty blocks with the railroad depot and a vast quantity of merchandise were cremated. The loss is variously estimated at from $10,000,000 to $15,000,000 about one-fourth of which is covered by insurance. Temporary help is urgently needed, but Phœnixlike, a new and improved town will promptly rise from the still warm ashes of the old, bricks taking the place of lumber in the buildings..... Ever since the refusal of the Dominion government, some months ago, to disallow the grant made to the Jesuits by the Quebec legislature to compensate them for losses incurred by English "usurpation" ages ago, the discord between the Protestants and Catholics, and especially the French-Canadians, across the border, has been growing stronger and more bitterly out-spoken. All over the country the Protestants have been ringing the tocsin against the increasingly aggressive priestly domination, and the French Catholics, especially those of the Province of Quebec, find in this an excuse for more compact organization. "The division of Canada into two necessarily hostile parts," "dissolution of the confederacy," "breaking up of the partnership" and "ultimate annexation to the United States," are threats or fears that find frequent expression, in this connection, in the Canadian papers.....

Cases in Point.

With most decided emphasis, we say Compound Oxygen is good—but, as a rule, people are dallient in accepting the good at hand, for no particular reason unless it is the fear of knavery.

But when this fear is removed by others, more venturesome than ourselves through anxiety and affliction, there is no further reason for doubt.

You have not to leap in the dark, for there are many beacons along the way. Here are a number.

PENFIELD, PA., Feb. 2, 1888.
"Thanks to the Lord and Compound Oxygen I believe I am well."
A. H. ROSENKRANS.

FRAZIER, PA., May 28, 1888.
"My recovery is perfectly marvelous. I feel as if I would like every sick person to try Compound Oxygen; it has done so much for me." MISS A. M. ROBB.

DANVILLE, N. Y., July 21, 1886.
"I feel truly Compound Oxygen *saved my life* and nearly four years have passed since I came to you in such a distressing condition, and to-day I can truly say I am *entirely well* and free from *asthma* and every symptom that pertains to it." MARY Y. HEDGES.

WEATHERFORD, TEXAS, April 1, 1888.
"You have my heartfelt gratitude for the good your Compound Oxygen has done me."
MRS. FRANKIE EDWARDS.

We publish a brochure of 200 pages, regarding the effects of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia; all chronic and nervous disorders. It will be sent, free of charge, to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa., or 120 Sutter Street, San Francisco, Cal.—*Adv.*

FOREIGN NEWS.

SATURDAY, August 10, 1889.

It appears as if the decrease in immigration to this country was at least in part due to the increase in immigration to the Argentine Republic. The number of European arrivals in Buenos Ayres in May was 21.655, and in June 21,952, or at a rate of 200,000 a year. Since January 1, there has been an influx of over 118.000 foreigners against 65.000 for the corresponding period last year. In view of the fact that in 1867 and the three following years less than 200,000 immigrants a year, and for two of these three years less than 150,000 a year reached the United States—a territory three times larger than the South American Republic—it is evident that the rush into the Argentine is phenomenal. The Republic encourages immigration by paying the passage money of the immigrants, as a rule, and often by making them concessions of land..... ... Felix Pyat, the French writer, dramatist and revolutionist, died Sunday at Paris, aged 79..... ....Tennyson was four score years old on Tuesday, August 6.....The wife of the famous Marshal Canrobert died suddenly at Paris, Tuesday. The Marshal is now 81 years old.... .....

FIVE HARVEST EXCURSIONS.

THE Burlington Route, C., B. & Q. R. R., will sell, on Tuesday, August 6th and 20th, September 10th and 24th, and October 8th, Harvest Excursion Tickets at *Half Rates* to points in the Farming Regions of the West, Southwest and Northwest. Limit 30 days. For circular giving details concerning Tickets, rates, time of trains, etc., and for descriptive land folder, call on your ticket agent, or address P. S. EUSTIS, Gen'l Pass. and Ticket Agent, Chicago, Ill.—*Adv.*

AGRICULTURAL NEWS.

SATURDAY, August 10, 1889.

"The Hillis Plantation Company" has been incorporated for the manufacture and sale of a substitute for coffee in New York.... .. C. H May, U. S. Consul-General to St. Petersburg, has made an exhaustive report to the State Department, on Russian agriculture and cereal trade. He says the exports of cereals from Russia in the past two years show an abnormal increase, due to three causes--First, the enormous crops gathered from both the black lands and the arable prairies; second, the depreciation of the paper rouble, and third, the foolish practice of systems of "corners" in the United States trade. The arable lands of Russia in Europe, excluding Poland, cover an area of 450,000 square miles. This must make Russia a formidable rival to the wheat-growers of America, and must effectually prevent grain dealers of this country cornering the markets of the world. Every corner attempted in this country gives Russia improved opportunity for disposing of her surplus. The nations of Western Europe will not pay artificial prices for grain so long as Russia can furnish such abundant and increasing supplies. These facts should teach market manipulators in this country a lesson, before our export trade is entirely ruined.... The Fourth Annual Exhibition of the New Hampshire State Grange Fair Association will be held September 10-12 ..... The 44th Annual Provincial Exhibition will be held in London, Ontario, Canada, September 9-14. Extensive preparations are being made, and liberal prizes are offered, and it is intended to make this one of the most interesting exhibitions ever held.....The Society of American Florists will hold its Fifth Annual Meeting at Buffalo, N. Y., August 20-22. An excellent programme has been prepared, reduced rates have been obtained from railroads, and a large attendance is expected. Wm. J. Stewart, secretary, 67 Bromfield Street, Boston, Mass.....The 23d Annual Fair of the Watertown Agricultural and Horse Association will be held at Watertown, Conn., September 24-26. A. H. Scovill, secretary, Watertown, Conn..... ..... The "Great St. Louis Fair and Zoological Gardens," will be held at St. Louis, October 7-12. All articles for competition are entered free, and any article exhibited may be sold. All articles and animals must be on the grounds on Saturday, October 5, and all awards will be made before visitors are admitted. All railroad and steamboat lines terminating in St. Louis offer a reduced rate of one fare for the round trip. $70,000 are offered in premiums. Arthur Uhl, secretary, St. Louis .....The Queens County Agricultural Society will hold its 48th annual exhibition at Mineola, Long Island, September 24-27. Secretary, Jacob Hicks, Old Westbury.....The Rock County Agricultural Society will hold its Second Annual Fair at Bassett, Nebraska, October 1-4. R. W. Blake, Long Pine, president, A. H. Gale, secretary..... ..... The Lane mill at New Orleans is turning out 30,000 yards of cotton bagging daily, and has orders on hand for 7,000,000 yards. This is an effectual way to settle the Jute Bagging Trust..... Florida is divided into six inspection districts, with an inspector of fertilizers over each.....The city of New York owns 781 horses, valued at $230,085. It costs about 28 cents per day to keep a fire department horse, and 78 cents for those used in the street-cleaning department..... It is said that a car-load of cheese is shipped daily from New York to California..... A Michigan cheese factory has shipped the June make of cheese directly to England realizing nine cents per pound..... The total receipts of live stock last week, at New York were 12,715 beeves, 98 cows, 5,669 calves, 34,593 sheep, 22,783 swine. This is an increase of about 50 per cent. over the corresponding week last year, on beeves, and a considerable falling off of other animals. There were shipped from this port, during the same time, 2,506 live cattle, 8,660 quarters of beef, 179 sheep. Boston shipments were 1,547 live cattle and 3,804 quarters of beef..... The Williams French Fattening Poultry Company expects to begin operations in Jersey City next week, and will fatten 100,000 head of poultry every 2.. days.....About 77,000,000 acres are planted to corn in this country this year, a slight increase over last year's acreage.....Experiments in the manufacture of sugar by the diffusion process at Lawrence, Louisiana, show a considerable increase in the yield over the mill method..... The Senate Irrigation Committee is on a pilgrimage through the West, and last Sunday distinguished itself by holding a public meeting at Aberdeen, Dakota, the first public meeting ever held on Sunday in the history of the Territory. They claim that irrigation by artesian wells is practicable..... The English are likely to have a Department of Agriculture, with a Minister of Agriculture in charge before the close of the present session of Parliament.....

Crops & Markets.

SATURDAY, August 10, 1889.

THE country at large has not been deluged with water to such an extent during the past, as during the preceding week, although there have been some heavy local rains. Light frosts have been reported from some parts of Illinois, and in the northwest, but no serious damage has resulted. The weather has been more favorable for farm work, and for securing the crops which have escaped complete destruction.

WHEAT has shown but little change, but the tendency is for advanced prices. But little thrashing has been done for the time of year, and much wheat has been badly damaged, if not entirely ruined by the long-continued rains. The receipts at interior points are very much lighter than at the same periods last year. The first new wheat consisting of two car-loads, arrived at Minneapolis, August 5, from Winnebago City, and sold for 82 cents for No. 2, and 88 cents for No. 1.

CORN prospects continue discouraging for nearly all sections. Kansas reports an immense crop, some placing the average at 105. Missouri also reports a good crop, but all other Western and Northwestern States will need a very late, warm fall to mature their crop. Texas also reports the best corn crop

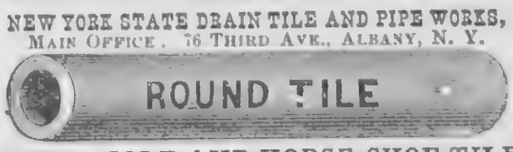
NEW YORK STATE DRAIN TILE AND PIPE WORKS,
MAIN OFFICE, 76 THIRD AVE., ALBANY, N. Y.



ROUND, SOLE AND HORSE-SHOE TILE,
Over 13 inches long. By cargo or smallest quantity. Our new improved machinery makes superior round and sole tile, excelling anything offered heretofore. First Premium wherever exhibited. Price-list on application. Vitrified Glazed Pipe and Tile Machines.

ever grown. The elevators are nearly empty at Baltimore, there being but 42,000 bushels on hand in all. This is due to decreased receipts.

OATS are a very heavy crop, but the crop has been much damaged by rain, and it is impossible to tell yet what the yield and quality will be.

HAY was a heavy crop, but reports show that much of it was secured in bad order. Hay is high now, and prime hay is likely to continue so.

POTATOES do not promise very well, especially on heavy and wet land. Reports of rot are general. The market is well supplied, but dealers will not purchase heavily, fearing further loss by decay; prices have advanced somewhat for good stock.

APPLES are likely to be a very short crop. Wayne County, N. Y. reports apples 25, plums 10, pears 90, peaches 30, grapes 40, raspberries 50. In regard to the apple crop in Western New York, our special correspondent writes:

I have traveled through Orleans, Niagara, Erie, Cattaraugus and Chautauqua Counties, and I am thoroughly convinced that with few exceptions there are no good apples there. Some trees have a few apples, but they are one-sided, cracked or rusted; defects supposed to be caused principally by the heavy frosts in early summer. I do not believe that Western New York will have enough first quality apples for its home use.

HOPS are reported badly damaged by blight in Oneida County, N. Y. In some cases it is said the late varieties will not pay for picking.

CHEESE prices have advanced slightly, at Utica and Little Falls.

BUTTER is dull for everything excepting the best grades. The market is overstocked with common and poor stock.

COTTON promises an average crop in South Carolina, Georgia and Florida. Dealers and manufacturers complain that growers have not exercised proper care in the selection of seed, and that the quality of the crop is deteriorating very rapidly in consequence. They say that unless this condition of affairs is changed, there will be increased competition with foreign cotton, which is coming to market in improved condition with each succeeding year. Certainly manufacturers cannot be blamed for buying the best of raw materials, though they be of foreign production.

THE WONDERFUL NEW GRAIN

(NOW READY FOR MAILING.)

RURAL NEW-YORKER CROSS-BRED AND HYBRID WHEATS.

A Circular containing full descriptions of these wonderful Wheats, mailed to applicants.

No. 2. Half wheat, half rye by parentage, though resembling wheat in all respects. Nearly as early to mature as rye. Stem purplish in color. Heads average over three inches long, eight breasts (or spikelets) to a side; chaff white, beardless. Often four grains to a breast, always three, of medium size, amber color and apparently hard.

No. 3. Half wheat, half rye by parentage, though resembling wheat in all respects. Nearly as early as rye to ripen. Tall yellow, stiff straw. Heads average three inches long, seven breasts to a side; chaff brown, bearded. Three grains to a breast, small to medium size, dark amber color

No. 50. Pure wheat cross. Early. Stem yellow. Heads average over three inches and somewhat club-shaped, seven breasts to a side; chaff white, beardless. Generally four grains to a breast, medium to small in size, hard, and of amber color.

No. 51. Pure wheat cross. Late. Stem yellow. Heads very long, averaging over four inches, nine breasts to a side; chaff brown, heavily bearded. From three to four grains to a breast, medium size, amber color. Stem tall and strong.

No. 53. Pure wheat cross. Medium to mature. Stems pink. Heads average nearly four inches. Breasts crowded—often ten to a side; chaff very clear and white, heavily bearded. Four grains to a spikelet—sometimes five—fair size, amber color. Inclined to club-head.

No. 55. Pure wheat cross. Medium to ripen. Stems yellow. Heads average nearly four inches. Eight breasts to a side; chaff white, heavily bearded; three to four grains to a breast, fair size, bright amber color, hard. Regular heads, that is, *not* inclined to club.

Price for packages containing twenty-five grains, 25 cents, or the collection of six sorts for $1.

A JERSEYMAN'S JOTTINGS.

ETHICS OF MARKETING.—Some years ago I listened to a discussion of the following topic: "If you know that a valuable gold mine is located under your neighbor's field and you also know that he would be glad to sell the field for the usual price of surrounding land, is it your duty to go and tell him about the gold mine, or would it be right to buy the land at his price and thus obtain possession of the mine?" This, I understand, is quite a favorite question in all text books on moral philosophy. The teachers all undertake to show that the right thing in the case is to tell the neighbor about the mine. In the discussion that I listened to it was decided that way. This is a favorite way to put the matter because it is all ideal. Gold mines are not very numerous in my part of the country, so that we can put down the moral law in great style when we discuss them. But I have often wondered how we would feel if the question were put in a more practical shape. Are we always so considerate of our neighbor's interests? Cholera breaks out among our hogs. We know it is a dangerous disease and that all the hogs are liable to it. What are we to do? Kill the sick hogs and sell the others just as soon as we can, or keep them all and lose a good proportion of them rather than sell any that may be diseased?

In one case we get our money back. Somebody has to suffer on the hogs; somebody has to eat the pork—we don't. In the other case we lose money that we cannot afford to lose, but we know that we have not put diseased pork on the market. Again, our hens have the cholera. We are sure enough that their eggs cannot be healthy. Do we tell our customers of this or do we sell the eggs and say nothing? Or our potatoes begin to rot. We may rush in and dig them, and send them at once to market, well knowing that the spores of the rot are in them and that somebody will have to suffer loss in consequence. These are matters that would be apt to provoke lively discussions at village debating societies.

The Potato Rot.—It looked last week as though the entire potato crop in our neighborhood was ruined. Farmers expected a dry season and so they put the potatoes on the lowest spots they could find. We have had a perfect deluge of rain. The ground has been like a wet sponge, and fields that gave promise of a great yield are now great masses of soft filth. It is a sickening sight. Many of our farmers depend upon potatoes for their winter cash, and it is the crop on which a good portion of the chemical fertilizers are used. Farmers are in a quandary as to what to do with the crop. Shall they dig the potatoes at once and try to sell them, or let them stay in the ground until the usual time for digging?

There seems to be a general belief that many farmers will dig at once and rush the product to the market. At present, I do not see that this belief is well founded. Marketmen say there is no rush yet at least to this market. If the potatoes are dug now they will continue to rot. During the past few days the weather has become clear and cool. If this continues the soil will at last dry out and the potatoes will be almost as safe in the ground as out of it. It might be well to dig those on lower ground earlier than usual, but unless we have more heavy rains I shall let my upland potatoes stay where they are for the present. I hope the damage will not prove so serious as farmers fear. It is true that reports of rot are general from all over the country, but the fact remains that we shall not know the real state of affairs until the potatoes are actually dug and sorted. Old potato growers assert that if one tuber in a hill becomes rotten there is no hope for the rest. I believe this depends to a great extent upon the sort of weather we have. A dry, cool August and September will make quite a change in the potato market. If potatoes are dug now, about the best thing that can be done with them is to spread them out in a thin layer in a dry cool place and sprinkle lime over them. They should also be picked over now and then and the rotten ones thrown out.

One result of the increased price of sugar will be a reduction in the amount consumed. Every member of the family will "fight the trust" by taking care to use just a little less sugar in the coffee, the tea or with the fruit. Let this saving amount to only a table-spoonful per day for the average family, and the total amount for the country would be immense. Let each family average a saving of an ounce per day, and it would mean a decreased daily sale of nearly 500,000 pounds for the country at large. This is a natural law. Whenever an article becomes outrageously high we all begin little economies. The sum total of these little economies rolls up an enormous volume. If potatoes are as scarce this winter as some people think they will be, the price will not go beyond a certain figure. Rather than pay more the consumers will eat more rice or buy more turnips and carrots.

The markets remain about the same. More chickens are coming; some very good lots are for sale. Eggs keep their price well. It will soon be time for the home-made sausage makers to capture the market. Suckling pigs are in demand but the supply is limited. Lima beans hold their price well and sweet corn is doing better than was expected. Tomatoes bring better prices than last year. The prospects for clover and Timothy seed point toward lower prices. Oats promise to be lower. There is no doubt that corn will be higher this winter than for several years past. Nobody can give anything definite about the potato crop yet. The general opinion is that the rot will not prove so bad as is now expected, except in a few localities. In any event the crop will be short and as Canada has had even more wet weather than we have had, the imports will not be exceptionally heavy. The first celery is here. Blackberries are slow of sale. A few huckleberries are to be found, but they are very poor specimens. Peaches are very poor. Pears are selling well with plums a little slow. Grape dealers expect good prices. Tropical fruits are everywhere.

Whenever the prospects for the corn crop are bad the English papers begin to urge their readers to drop corn-meal partially at least—and substitute linseed-meal. This year they have begun early on this advice. I think it would be a good plan for American farmers—Eastern ones particularly—to study out this matter too. How many have ever fed linseed-meal? How many know where to get it? If corn is going to rise in price this winter I want to know more about linseed-meal. What is its intrinsic value for feeding? I would like to know so that when the price of corn goes above this value, I can try the linseed. I think it will pay farmers well to look into such matters.

MAGAZINE REVIEWS.

THE AUGUST CENTURY fully equals its contemporaries in its articles relating to out-door life, excursions, natural history, etc. It is truly a "Midsummer Holiday Number." The "Stream of Pleasure" is an illustrated account of a trip from Oxford down the Thames in a skiff, by Joseph and Elizabeth Robbins Pennell. A very entertaining account is given of their trip down this popular water-way, passing the locks, dodging the bridges, exploring the tributary streams and adjacent towns, and running into and escaping from all sorts of possible and impossible dangers. "Afternoon at a Ranch" is the title of the picture in the Far West series. S. Weir Mitchell describes the different species of venomous serpents in this country and in India in the article "The Poison of Serpents." There are in this country very few poisonous serpents, and these are continually diminishing in numbers. India is pre-eminently the home of this class, there being 15 different genera. The rattlesnake is the most common in America. The article contains several illustrations of this reptile, as well as of other species. What to do when bitten by a poisonous snake is also told. The Century has caught the "symposium" fever. The artists are the contributors of a number of articles dealing with their branch of the business. "Wood-engravers in Camp" by Frank French, tells how a small party of wood-engravers made a camping-out excursion to the regions near Hockanum, Mass. The article is illustrated with engravings taken by the author, of some of the quaint residents of the locality visited and also of a "Hockanum Wild Flower," of the genus girl. Other articles are "Originality in Wood-engraving," "Painter-engraving," and "The New School of Engraving," all illustrated. Frederic Remington contributes "Artist Wanderings Among the Cheyennes," with profuse illustrations. He tells how the Cheyennes are made useful as policemen, scouts, etc. Mr. Kennan's paper deals with "State Criminals at the Kara Mines." Dark as are the pictures presented in these papers, there is an occasional ray of light, and this article brings to the fore Col. (since made General) Kononovich, at that time the governor of the mines and prisons at Kara, a very conscientious, merciful man. The Lincoln History deals with events attending Mr. Lincoln's renomination and the exciting campaign during the summer of '64. In commemoration of Tennyson's 80th birthday, a fine engraving of the poet laureate is given as a frontispiece. Henry Van Dyke also contributes "The Bible in Tennyson." There are numerous choice bits of verse, and all conspire to make the number an exceptionally strong one. The Century Company, New York.

THE COSMOPOLITAN CO. claims to furnish a first-class magazine at a low price, and, judging by the August number, the claim is well founded. "Social Life at Ottawa" is the first article, and gives a very good description of the customs and manners at the Canadian capital. Illustrations and descriptions are given of the Government House, and of several of the leaders of society. Richard Wheatley in "The Caged Tigers of Santa Rosa," describes the Chiricahua Apaches who were formerly confined in Fort Pickens on Santa Rosa Island, Fla., but who have since been transferred to Mount Vernon, Alabama. "The Children of Arachne" by Emile Blanchard, deals with different species of spiders and describes their curious habits and homes. The European Trap-door Spider is illustrated, which not only makes her house, but closes it with a trap-door hung on hinges when she retires. Then there are the water spiders which build their houses securely beneath the surface, and then carry bubbles of air down to fill them. Many other kinds are illustrated and described, the whole article forming a very interesting lesson in natural history. Kate Douglas Wiggin asks "What Shall Children Read?" and then proceeds to give some very sensible advice on this all-important subject. W. W. Thomas, Jr. tells about "A Trip to Dalecarlia," and describes in a very pleasant way the curious sights in that far-northern land; its brightly-clad people, pretty-faced maidens, with their odd ways and quaint customs. Frederick Douglass gives a paper—"Reminiscences,"—dealing with the agitation period. It is difficult to realize that this vigorous, scholarly writer was once an illiterate slave. Cardinal Gibbons contributes "The Dignity, Rights and Responsibility of Labor." "An American Soldier in China" is an account of the strange career of General Frederick Ward, whose military genius won him great distinction in the Orient. "A Bourgeois Wedding in the South of France," "French Horses and the Grand Prix," "Social Problems," etc., complete the number. The publishers do not indulge their readers in much poetry. The Cosmopolitan Publishing Company, New York.

Educational.

THE COUNTRY SCHOOL.

THE COUNTRY SCHOOL is a unit of great value in the national problem. How shall we improve it? In answer to this question may I suggest:

1. Is not the intensity of American business life too much carried into the primary schools, drawing too heavily upon the nervous force of American childhood?

2. Will not better and more lasting results be attained by "making haste" more "slowly?"

3. May not fewer hours in the school-room supplemented by out-door and industrial teaching, be better for the child physically as well as mentally, and as a preparation for active life?

4. Can not the country child, while attending the district school, become so well acquainted with, and made so to delight in the pursuits of agriculture and horticulture, be led so gently and pleasantly into such an intimate acquaintance with, and love of Nature, as often to determine the trend of later life in the direction of rural pursuits, or of scientific inquiry?

5. Will not all this uplift rural life to a higher plane?

Well, how? Perhaps I cannot tell you. The plan will certainly require different teachers, to some extent, or at least teachers better informed in some directions. Possibly almost any bright girl of 17 tolerably well instructed in the usual common-school studies, may satisfactorily teach the rudiments of arithmetic, geography, and grammar; but to take a school of 30 or 40 children of various grades of mental capacity, and train them into accurate observers, close thinkers, and good reasoners with reference to the common things of their lives, and their surroundings, is quite a different matter, and needs more thoughtful and better-read teachers than many found in our country schools. In no school is needed teachers of a better grade of intellect than in the primary, and perhaps in no school can better use be made of a broad scientific and literary culture.

It would seem as if a part of the time usually devoted to arithmetic, grammar and geography, useful as these branches are, might be better employed.

Why should a bright child require half a dozen years to master these branches sufficiently for all usual practical uses? Suppose we take one of these branches at a time, and concentrate study upon it. Should not one hour daily, under a competent teacher, give an intelligent boy or girl of 12 or 14, as good a knowledge of either of these branches as is usually had in all the years spent in the common school? If not, why not?

Let there be no more than four in summer, and no more than three hours of in-door school work, and but one hour at one time. Allow to one of these main studies one hour's work; then reading, and reading to understand; writing—and as soon as possible writing to express ideas; drawing, and spelling; and after this oral lectures by the teacher on any topic, scientific, literary or historical, that may be thought advisable. After that let all go out-of-doors. Make each school an experiment station of agriculture and horticulture. Let the teacher conduct expeditions to neighboring farms, to the fields, the woods. Let the children learn how crops are grown and why so grown; what obstacles meet the farmer, the fruit-grower, the gardener, and how they may be surmounted. Teach them of the soil, the plant. Let each child conduct experiments of his own. Make a part of the school grounds a garden. Am I writing of Utopia? Would not the outcome of all this be a greater love of, and an intelligent interest in rural life, that would produce a class of wide-awake agriculturists, of thorough scientists, and of reverent seekers after truth and God? But it is hard to get out of deeply-worn ruts.

Let us have no high-pressure system of conducting our country schools. Let us remember that children have bodies—that physical as well as mental strength is necessary to build up a strong nation. Let us remember that brains crowded with undigested and indigestible facts of no special value in ordinary circumstances, may not be as useful organs as those trained to observe accurately, think clearly, and bring knowledge to bear promptly on the necessities of actual life.

MRS. M. P. A. CROZIER.

BACTERIA IN MILK AND ITS PRODUCTS.—Bulletin No. 4 from the Storrs Experiment Station. Storrs, Tolland County, Connecticut, prepared by Professor H. W. Conn.

What are bacteria? The term is now in common use. If one is to obtain any good from scientific agriculture he must have at least a general idea of what bacteria are, just as he must know that albuminoids and carbohydrates represent two classes of substances as distinct as beef-steak and corn-meal mush. In speaking of bacteria the reader must understand that what is meant is a class of very small organisms which produce fermentation, such as the raising of bread or fermenting of cider, rotting of potatoes, decay of wood, etc. etc. Bacteria, yeasts and moulds all belong to the same family, are somewhat alike, and are commonly called by the same name—bacteria.

Milk is a medium in which bacteria grow readily. It is the development of the bacteria that causes milk to sour and cream to ripen. Remembering this fact will give a clearer idea of what is meant by bacteria. If milk, cream or butter can be kept entirely free from bacteria, the ordinary changes do not take place in them. For example: by heating milk to a boiling temperature for a few minutes for three successive days and keeping it sealed absolutely air-tight, the milk will keep sweet indefinitely. The heat kills the bacteria. Excluding the air prevents a new lot from entering.

This heating and air-tight sealing have been hailed in Norway as a "new discovery." Milk so treated is said to be "sterilized" and can be shipped many miles in safety. Milk or cream under ordinary conditions cannot be kept free from bacteria. One very common cause of contamination of milk is from vessels in which milk is placed. These, unless washed in boiling water, contain bacteria clinging to their walls. The action of the bacteria indicates clearly the absolute necessity of using boiling water for cleaning dairy utensils. We have seen people who clean milk pans by placing them in a pile, one resting in another, and then pouring hot water into the upper pan. When this is washed the water is poured into the pan below it and so on. The best dairymen take pains to apply boiling water to each pan, and we may see now that their practice is based upon scientific principles, because it is only by submitting each to a very high temperature that the invisible bacteria can be destroyed. It would be wiser even to place the pans in a hot oven for a short time after washing.

A mild heat favors the growth of bacteria while cold retards it. Hence we see the advantage of keeping milk cold and cream warm. And this matter of the temperature of cream gives occasion for an important discussion in this bulletin, of the objects of the ripening of cream. There seem to be two chief objects in this process. The butter will separate more readily from ripened cream and the churning will be easier. Again, many people believe that the butter made from ripened cream will keep longer than butter made from sweet cream. Dr. Babcock shows, in bulletin No. 18 from the Wisconsin Station, that shortly after the milk is drawn from the cow there appears "a fine, inappreciable network of fibers which produce in the milk a slight thickening somewhat like the clotting of blood." This he calls "fibrin." It will readily putrefy. When the cream rises some of this "fibrin" is entangled with it and is skimmed off with the cream. Bacteria cannot live upon pure fat. This "fibrin" attracts them and they feed upon it and decompose it Churning is a mechanical process. After the "fibrin" is thus partly dissolved by the action of the bacteria, the butter globules may be more easily shaken free. And this presence of "fibrin" may explain the better-keeping quality of some butters.

If cream is churned before the "fibrin" has become decomposed *i. e.* before the cream is ripe, the butter will naturally contain more of the "fibrin" than will butter from thoroughly "ripened" cream, and, naturally, the more "fibrin" the more bacteria.

Prof. Babcock has shown that the quicker the cream rises the less will be the amount of "fibrin" entangled with it. When cream is separated by a centrifugal machine a good part of the "fibrin" settles at the drum of the machine and less passes into the cream. It would seem therefore that such cream requires less ripening than that raised by a longer process.

THE INFLUENCE OF CERTAIN CONDITIONS UPON THE SPROUTING OF SEEDS.—This is the title of bulletin No. 7 of the experiment station at Cornell University. Prof. Bailey has conducted a number of experiments, the results of which are recorded in the bulletin. The experiments are of greater interest to the market gardener or the seedsman than to the average farmer.

Prof. B. concludes that the percentage of impurities or adulterations in seeds as ordinarily supplied by seedsmen is very small. In general, he found the more important seeds free from impurities. He says that "the endeavor to determine the relative merits and honesty of seedsmen, by means of testing their seeds, is the merest folly."

The germinating tests appear to have been carefully conducted. Here are a few of the indicated results:

Variations in temperature may cause variations in rapidity of sprouting. A constant temperature is best, and about 70 degrees seems to be best suited. There is a tolerably well-defined temperature specially suited to each species of plant.

A comparatively small amount of water gives quickest and largest results. Soaking seeds before planting does not seem to hasten sprouting if planting time is reckoned from the time the plants are put to soak.

When light has any influence, it retards or wholly prevents sprouting, but the effects of light are different in different species.

Heavy seeds generally germinate better than light ones of the same sample.

If there is any variation in vitality in reference to color, it is usually found that the stronger sproutings occur in the darker colored seeds.

Northern-grown corn appears to germinate quicker than Southern-grown corn. It is expected that seeds of most species will give similar results.

CONNECTICUT EXPERIMENT STATION.—Bulletins 98 and 99 discuss Home Mixed Fertilizers and Fertilizer Analyses. It appears that quite a good many farmers in Connecticut mix their own fertilizers instead of buying the prepared mixture sold by the fertilizer dealers. The various ingredients are bought in separate forms and an effort is made so to study the needs of a certain farm or a certain field that a fertilizer can be produced that will prove better adapted to the needs of that particular farm or field than any of the standard fertilizers that are made in large quantities and sold for use on widely different soils and situations. The continued use of large quantities of chemical fertilizers generally leads to experiments with home-mixed fertilizers. In some cases the farmer convinces himself that it does not pay to do the work. In others he concludes that his labor is well spent. In still others he thinks that a quantity of the standard fertilizer with a bag per acre of some one ingredient added will suit his farm well enough. The R. N.-Y. found an example of this at Cranbury, N. J. One of the best farmers there convinced himself by experiment that his farm needed extra quantities of potash. So in addition to a large dressing of the Mapes potato manure, he applies a bag of muriate of potash to each acre. He thinks this pays him.

Some of the Connecticut farmers seem to have made a regular study of home-mixed fertilizers. This is due to the fact that the Connecticut Experiment Station has made a special study of fertilizer ingredients and by its system of conducting experiments on farms in various parts of the State has greatly encouraged practical investigations on the part of farmers. In this bulletin (No. 98) are given lists of the ingredients used in 11 mixtures, with analyses and estimated cost. We give three of these mixtures. All who are interested in the subject should send for this bulletin which is one of the most important that Eastern farmers can get.

The following is designed as a "mixture for general use:"

834	pounds	Dissolved Bone Black,	costing	.....	$10.43
666	"	Tankage,	"	.....	9.32
208	"	Sulphate of Ammonia,	"	.....	7.80
292	"	Muriate of Potash,	"	.....	5.84
2000	"				$33.39
		Add freight to New Haven			1.60
		Total cost of raw material			$34.99

This is a mixture for corn.

450	pounds	Tankage,	costing	.....	$6.44
450	"	Ground Bone	"	.....	6.77
232	"	Sulphate of Ammonia,	"	.....	8.65
384	"	Dissolved Bone Black,	"	.....	4.99
305	"	Muriate of Potash,	"	.....	6.34
179	"	H'gh-g'de S'lp'te of Potash	"	.....	5.48
—	"		"		
2000	"		"		$38.67

And this for potatoes.

500	pounds	Sulphate of Ammonia,	costing	.....	$18.65
2500	"	Tankage,	"	.....	35.75
2500	"	Ground Bone,	"	.....	37.63
2500	"	Dissolved Bone Black,	"	.....	32.50
750	"	Muriate of Potash,	"	.....	15.60
550	"	Sulphate of Potash,	"	.....	16.88
—	"		"		
9,300					$156.96

Cost of the materials delivered $33.75 per ton.

Analyses of these mixtures were made at the Connecticut Station, with the following results: The valuation is figured on the basis used when estimating the values of standard fertilizers. The last column, "cost," gives the actual cost of the chemicals before mixing. The quantities of nitrogen, phosphoric acid and potash are what were actually found in the mixtures.

	Nitrogen.	Phosphoric acid.	Potash.	Valuation per ton.	Cost.
General Mixture.	4.94	8.80	7.89	$39.02	$34 99
Corn Manure.....	4.99	9.19	14.07	47 48	38.67
Potato Manure...	3.95	12.47	7.41	39.20	38.75

It will thus be seen that the differences in valuation and cost per ton were $5.03, $8 81 and $5.45.

The director says that the advantages claimed for home-mixing are:

1. Each ingredient can be separately examined by the purchaser and if necessary sent to the experiment station for analysis. The detection of inferior forms of nitrogen or phosphoric acid is much easier and more certain in a single article than in a mixture.

2. It is self evident that an intelligent farmer by home-mixing is better able than any one else can be to adapt the composition of his fertilizers to the special requirements of his land as well as of his crop, and how greatly the soil-requirements vary in this State, even over a small area, is strikingly shown by the field experiments annually reported by our farmers through the stations.

3 It is claimed that the same quantity and quality of plant food costs much less in home-mixtures than in ready-made mixtures because the cash purchaser of fertilizer chemicals deals directly with the importer or manufacturer, not with the middleman or retailer, and receives quotations without reference to the prices asked in his neighborhood by retailers of the same goods.

There is no longer any question as to the expediency of home-mixing in many cases. From such raw materials as are in our markets, without the aid of milling machinery, mixtures can be and *are* annually made on the farm which are uniform in quality, fine and dry and equal in all respects to the best ready-made fertilizers.

He also says that the economy of home-mixing depends, of course, on the prices which sellers of mixed goods are willing to take and on the cost of fertilizer-chemicals delivered as near the farm as mixed goods can be bought. There is always a chance for the farmer who studies the market and the needs of his farm to save enough in the purchase of his fertilizers to make just the difference between profit and loss on a crop, and in farming, as in everything else where competition is close, profit usually comes from care in these small margins of expense. Perhaps home-mixtures are not indeed always and everywhere cheaper or more economical than commercial mixtures, but it will often happen that money can be saved by the timely purchase of raw materials and their mixture on the farm. Each individual farmer ought to be the best or only judge of the economy of home-mixing in his particular case, as well as of the "formulas" which are best adapted to his soil and crops.

In bulletin No. 99 we find an analysis of wool waste. The specimen examined contained:

Nitrogen.....	2.87	per cent.
Phosphoric Acid.....	.81	" "
Potash.....	5.38	" "

It was worth $10.57 per ton as a manure and was considered suitable for fruit trees, grape vines or grass.

Damaged corn meal costing $1.80 per ton contained about twice as much nitrogen as stable manure and about as much phosphoric acid and potash as stable manure. It was recommended as a suitable manure for light, sandy soils.

The director of the station points out the fact that the fertilizing value of fine bone is much greater than that of coarse bone. The latter may lie in the ground for years while very fine bone is readily decomposed and taken up by plants.

ENEMIES OF THE WHEAT APHIS.—This is the title of bulletin No. 51 of the Michigan Experiment Station. It is prepared by Prof. A. J. Cook and contains illustrations and descriptions of the various parasites that prey upon the wheat aphis.

WILBER H. MURRAY Company, Cincinnati, O.—A special offer of harness, buggies, roadcarts, etc. Send for catalogue or read advertisement.

Law.

"Every Man is presumed to know the Law. Nine-tenths of all Litigation arises from Ignorance of Law."

NEW YORK LAW AGAINST POACHERS OF GAME.

T. L. M., Lewis County, N. Y.—Is there in this State any law which will enable a man to protect the fish in a stream flowing through his farm? A fisherman catches fish in a stream passing through my farm, but in doing so he walks in the bed of the stream; can I hold him liable for damages for fishing in forbidden waters?

ANS.—The laws in this State relating to the taking of fish and the hunting of wild game are alike in their general provisions. It is provided that any person who shall knowingly trespass upon inclosed or cultivated lands, for the purpose of shooting or hunting any game protected by the act, or shall take any fish from private ponds or private streams not stocked in whole or in part by the State, or after public notice has been given by the owner or occupant thereof, shall be liable to such owner or occupant, in addition to the actual damages sustained, in exemplary damages to an amount not exceeding $25 or less than $15. The public notice is to be given by erecting sign-boards at least one foot square upon at least every 50 acres, upon or near the lot lines of the premises, or upon or near the shores or banks of any lake, pond or stream in at least two conspicuous places. For this notice may be substituted a written or printed warning served personally on the offender. If the inquirer owns the land on both sides of the stream, he owns the entire bed of the stream, and the fisherman traveling on it was, of course, a trespasser.

BOOMING!!!

Yes, that's the only word that will express it. We did more business last month than any month since our existence. We have been almost rushed to death with orders, in fact we have actually got behind, and are now compelled to still further

ENLARGE AND IMPROVE OUR MAMMOTH WORKS

and the end of this month will see us in better shape to fill orders than any factory in existence.

We think we hear you say, "What remarkable success the "Murray" people have had," and we say in reply, there is nothing remarkable about it. We simply started out to do an *honest, straight-forward business,* to sell our "Murray" Buggies and Harness, solely on their merits & low prices; to *stick to the people* and not to the **POOLS AND TRUSTS** which are only to *"Enrich the Rich"* and *"Impoverish the Poor."*

By the **Latest Improved Machinery, Skilled Workmen** and **Long Experience** in the **BUGGY AND HARNESS** business, we are enabled to put the **"MURRAY"** Goods on the market at

PRICES THAT DEFY COMPETITION. SOME PRICES THAT TALK.

BUGGIES!

If you value your money, don't buy elsewhere before seeing our Catalogue.

$15.00 for one of the best Road Carts made

$55.95 for either a Side Bar or End Spring Murray Buggy

$108.00 for our Murray Canopy Top Side Bar Surreys

$109.00 for our elegant Jump Seat Surrey

We're not afraid to show our prices, for we know they can't be beat.

! ! $66.90 ! !

We're the only Factory in the U. S. that CAN DO THIS!!!

Just think, sixty-six dollars and ninety cents for a "Murray" Brewster Side-Bar Top Buggy, and a set of "Murray" Single Strap Track Harness. It seems strange, but it's true, and we are the only Firm that can do it.

HARNESS!

If you want the Best and Cheapest, buy of us.

$5.95 for our No. 1 Murray Single Buggy Harness

$9.85 for our No. 2 Murray Single Buggy Harness

$10.95 for our No. 3 Murray Single Buggy Harness

$15.20 for our No. 4 Murray Double Buggy Harness

$19.80 for our No. 5 Murray Double Buggy Harness

Remember, that every harness that leaves our factory is made of the best No. 1 OAK TANNED LEATHER.

HONEST GOODS, LOW PRICES and **COURTEOUS TREATMENT TO OUR CUSTOMERS** is our motto.

Call and see or write to us for our Catalogue and Price List. No middle men between us and the consumer.

MONEY TO BE MADE.

By those who are willing to make a business of CANVASSING for the RURAL NEW-YORKER. We are prepared to guarantee

BETTER WAGES THAN CAN BE SECURED FROM ANY OTHER PAPER.

Here are three plans for paying agents. You may take your choice:

1. **Liberal cash Commissions on yearly or short-term subscriptions.**
2. **Liberal Premium rates on any article made or sold in America.**
3. **Good wages in Cash to all who prove themselves successful as canvassers.**

BEGIN NOW. We want to hear from you. Write us how you wish to be paid for your work, and we will arrange with you for profitable employment.

THIS IS A SAMPLE NUMBER OF THE RURAL NEW-YORKER.

We Make a Liberal Short-Term Offer:

The only way to become acquainted with a paper is to read it for a few weeks; then you can tell whether it is worth any thing to you or not. Try the RURAL in this way. It will be worth your while.

"FATHER USED TO TAKE IT!"

Thousands of people have said this at the mention of the RURAL'S name. *Enough Said!* Try the RURAL a few weeks, and you will find that father's paper is plenty good enough for the son.

What They Think of Us! Read This.

Here is a letter from a Wisconsin lady. It speaks for itself. We are prepared to let it take the place of an extended argument to prove the value and usefulness of the RURAL NEW YORKER:

"I am a widow and undertook to support my three children by teaching school in the central part of the State, but my oldest son had no taste or inclination for anything but farming. All his cry was: 'Oh, mamma! let's get a farm where we can have cattle and horses!' I was unable to buy a farm, so I came up here and took a homestead in the wilderness when he was 12 years old, and took the RURAL NEW-YORKER for him. I had to teach three miles from the homestead, and the next year my daughter, then 16, and this son, kept house at home, and my youngest son, 10 years, and myself kept house where I was teaching and walked home every Friday after school. But my health gave out after two terms, and we failed last February to get the money to renew our subscription. But the other day we had a dollar. There were so many ways to use it that we held a consultation to determine how to spend it. When my oldest son came to speak he said: 'Send for the RURAL for the rest of the year. I would rather go without my dinner every day for a month than to go without the RURAL any longer.

OTHERS OFFER OCEANS OF OUTLOOKS

NOTES ON A SEASON'S WORK.

T. B. TERRY.

Shallow cultivation for potatoes; a careless boy's work; Mammoth Clover for hay; ripens at a time when farmers are not so busy; experience with clover-root beetle; dodging the midge.

I WAS riding along the road, when I noticed a boy cultivating in a field of potatoes. This was early in July. I climbed over the fence to see what he was doing. I found the work just what I expected. The cultivator had five small teeth. It was set just as wide as it would go between the plants without tearing them up. There was a wheel on, which kept up the front teeth to a reasonable depth; but the boy was "riding" on the handles, and the back teeth were going down four or five inches, cutting off a large part of the roots that the young plants had thrown out, even across the rows. In this cool, wet season the roots seemed nearer the top than I ever saw them before.

Where was the owner of that boy? Well, I don't know; but I do know that I would not have had that boy go through my potato field in that way, at that time, for $20 an acre. Whether the farmer did not understand the growth of potato roots, and hadn't common sense enough to know that it was foolish to tear off half the roots and put the plants to the expense of growing them over again, or whether he knew this and started the boy all right and then failed to watch him, I know not. The result was the same anyway.

Before I left home I talked some plain English to my man (not boy). I said: "Now, see here; don't you let the side teeth of that cultivator go more than an inch and a-half deep in one single spot in this field. One inch deep will do. Look every few minutes and see just what you are doing. Keep the cultivator just as I tell you or do nothing." Then I explained to him the reason for this. Much of my cultivating was done with Breed's Weeder, a very light slanting-tooth harrow, that hardly stirred the ground more than one inch deep. My first cultivation of the potatoes, before they came up, with the Hudson Bicycle sulky cultivator, was as deep as two horses could well give. After that, shallow cultivation was given. Not only was the wheel set to keep the front teeth out; but I knew whether any one was riding on the handles or not.

The last half of June was very wet with us. It was just impossible to do anything about curing clover. The Fourth of July it cleared up, and the weather has been good for securing crops since then. But this brought haying and harvesting all together, and kept farmers from the corn and potato fields, where tillage was greatly needed. The clover cut in July, however, was past its best. I notice two farmers who have things in better shape than the majority. They have mostly Mammoth Clover, with a little Timothy in it. They are just cutting it now, after the middle of July, the clover being in full bloom. Their wheat is secured and they have had time to attend to their crops. Their potatoes now need no more attention, and their corn is laid by and they can attend to their clover as well as not. This strikes me as a pretty good plan. It certainly puts some of the haying forward to a time when the weather is usually better for curing and when the farmer is less busy.

Is the hay from large clover as good? They tell me it is about as good, if the seed is sown thickly. Certainly it is far better, cut in the full blossom, now, than hay made from the small clover, which is about dead. Many tons of such are being cut.

I mowed one piece of my small clover about the 15th of May, when it was about one foot high, and left it on a field for a mulch. There is a grand crop there now, in full bloom, promising a good crop of seed, which will ripen at a time when we can attend to it. I wished in June that all had been treated in this way. The piece thus served, and the Mammoth Clover, escapes the midge which usually ruins the ordinary second crop of small clover for seed making.

We have the clover-root beetle. The tap-roots of the plants were mostly eaten out last fall. It was a question how that clover would do if left to stand another year. A neighbor left a field. It had been mowed but one year. It started pretty well this spring, the clover throwing out numerous fibrous roots. But along in June these seemed unable to sustain the plants any longer and the clover began to die. There is only one way for us now, and that is to mow the clover one year and then plow that fall or the next spring for some other crop. The beetle then seems to do little harm. My clover last year matured a second crop that would have made two loads per acre of hay, in spite of the root beetle.

Then is the time when clover sod should be plowed any way, as soon as the roots have at-

A GROUP OF GRADE JERSEYS. From a Photograph Fig. 209 Page 556.

tained their maximum growth. Raise big crops one year and then plow it and raise big crops of something else. This is the way to make the most out of it. The clover beetle will not hurt them. It may be a blessing to some others.

Summit County, O.

THE DOUBLE-ROWED SYSTEM OF PLANTING CORN.

THIS plan of planting corn will give more stalks and sunshine to the acre than any other, and experiments have shown that 17 inches in the drill is about as close as our large corn will grow and produce ears, and I have one acre planted this year on very rich and highly manured land on the double-rowed system, viz: double rows five feet wide w th hills 17 inches lengthwise and the double rows 17 inches between them. This plan will give about 11,500 stalks per acre. Allowing 106 ears to the bushel and one ear to each stalk, this will be about 108 bushels per acre, or two ears to the stalk would be 216 bushels per acre.

In order to get the same number of stalks or hills to the acre on the single-rowed system, the rows must stand only 30 inches apart, which is too close to admit the necessary sunshine and air to form the ears; while the double-rowed system will afford a space 43 inches wide between them for sunshine and air.

I used 12-inch sweeps for plowing out one furrow between the narrow rows and I plowed two furrows with a one-horse cultivator in wide rows which lessened by one-third the number of times I had to go through the rows,

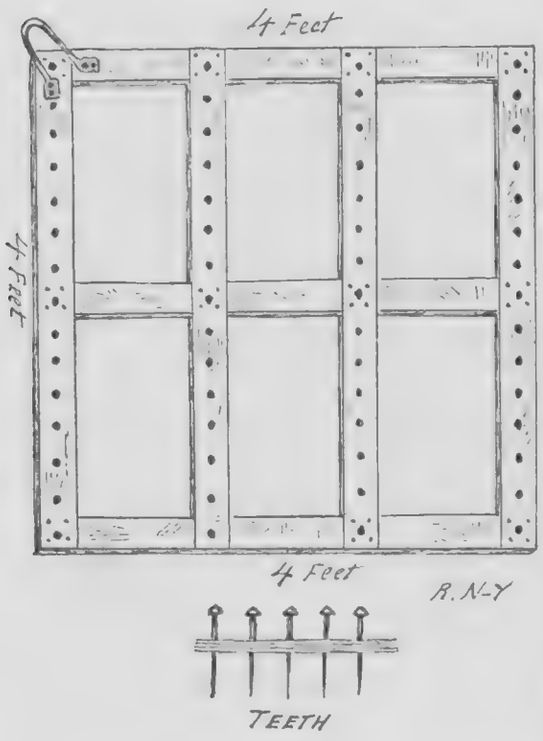

Fig. 210.

and weeds and grass cannot stand the shade in the double rows as well as in the single rows.

Rural Topics.

AT A FAIR.

FRED GRUNDY.

"SAY, Bill, ain't ye goin' to see the race?"

"Why, I hadn't thought of it, John; what sort of a race is it?"

"Runnin', Boomer an' Scooter an' several more. Big thing, I tell ye! Miss half yer life if ye fail to see it. Come along, we'll be late if we don't hurry."

The first speaker was a brown-faced, hard-handed, loud-talking, "horsey" farmer, plainly dressed, evidently one of those late and early hustlers who believe there is wealth in "elbow grease," and health in pork, beans, cabbage, corn bread and molasses. The second was also a farmer; a rather neatly-dressed, pleasant, easy-going sort of a chap, and evidently one who believed in newspapers, and enjoyed pictures, flowers, nice clothes, etc. The place was the fair grounds of a noted agricultural society.

To pick up a few notes I followed this pair to the race track. John elbowed his way through the crowd and led Bill to a seat in the amphitheater, not far from the line. I took a position just above them.

"Have ye seen the hosses, Bill?" asked John.

"No," replied Bill, "Nettie and I were looking at the poultry and machinery and fine hogs so long that I didn't get time to go down to the horse stalls. She wants to get a fine rooster and a new churn, and I was sort o' looking after a good pig."

"Gosh! I went amongst the hosses soon's I got on the grounds. I don't give a cent for chickens! Hosses is my holt! Last year I

Fig. 211.

got a p'inter from a jockey an' won $17 on the races inside o' 20 minutes!"

"Is that so!" exclaimed Bill, in astonishment.

"You bet it is. Best day's work I ever done in my life! Now, don't say a word about it to nobody, but I've got $10, even up, on Boomer. You jest ought to see him—you will pretty soon, I see the marshal clearing the track now. Oh, but he's a buster! He's in *prime* condition—fit to run fer a million. Yes sir; Boomer's the winner, an' don't ye forget it!"

Just then a languid-looking chap dressed in checkered clothes and gold-rimmed spectacles halted in front of John and drawled out: "Did you say that Boomah would ween?"

"You bet I did!" responded John, emphatically.

"Bet you aw fivah he don't, awnd put tha monee in your friend's hawnds. He's a awnest mawn, I know be his looks."

John placed $5 in Bill's hand and the dude covered it.

"Bet you awnother fivah I ween the bet," said the dude. $5 more were placed in Bill's hands.

"Any moah?" queried the dude.

"I'd go you more if I had it," replied John.

The horses appeared and after some preliminary monkeying ran twice around the ring, while John and the multitude yelled themselves hoarse. Boomer led finely up to the last quarter when Scooter ran ahead and came in an easy winner.

John's face turned yellow. "Don't say nothin' about this, Bill," said he, as with a sickly smile on his features he quietly arose and slipped away through the crowd.

I followed him to the "Fine Art Hall,"

Fig. 212.

which he entered. As I came in at another door I overheard him speaking to a tired-looking woman who was seated on a small bench fanning a worrying and sweating babe that lay on her lap. "Come, Jane," said he, shortly, "it's time to go home. Where's Tommy?"

"He's just went out with Sammy Smith. He begged me for ten cents to take him in one of them side-shows where there was something funny. I guess he's down there now."

"What do ye let him fool away money on such trash fer? They're reg'lar swindlers. Ye are old enough to hev more sense an' know better. I'll side-show him when I find him!"

As they started toward their wagon I heard the woman say: "I didn't get to see nothing. Belle was so cross she wouldn't walk, and she is too heavy for me to carry. I wisht you'd o'helped me carry her round awhile so I could have seen a little of something."

Christian County, Ill.

The Herdsman.

THE MUCH-DESIRED COW.

L. F. ALLEN.

I AM asked the following questions:

1. Have you ever been able to secure a grade or cross-bred animal that could be called a success both in the dairy and at the block?

2. Has there ever been a period in American agriculture when what is known as the "general-purpose" cow paid? If so, of what breed was she?

1. In my experience of more than 50 years breeding dairy cows, I have succeeded in rearing many of what may be called "general-purpose" animals; that is, cows good for the

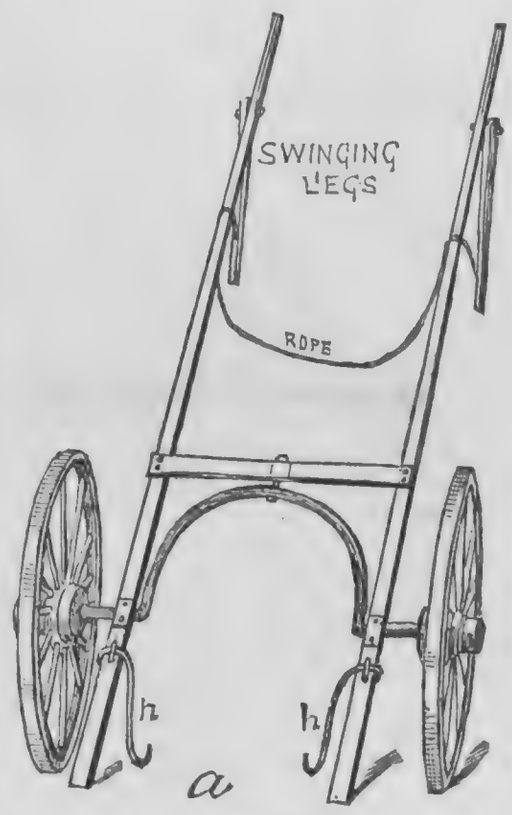

Fig. 213.

dairy and for good carcasses of beef at any age at which the owner may choose to devote them to the latter purpose. Those "general-purpose" cows were composed of grade animals chiefly from thoroughbred Short-horn bulls of good milking descent, and well selected common or native stock, their produce being various grades, extending from half-bred Short-horn higher up.

In explanation of these grades and my choice of the Short-horn sires, I will remark that the early importations of that breed into our Eastern States—say from 1818 to 1830—were from the best herds of the English breeders who attached great value to the dairy as well as to the beef qualities of their herds, being thoroughbreds, with pedigrees recorded in the early volumes of the English Herd Book. Large numbers of cows from the imported bulls were bred in New England and Pennsylvania and other Eastern States, proving first-class for general purposes of the thoughtful farmer, and such stock is still bred in various sections of our Northern and Middle States, as good general-purpose cows as can be found, but no distinct breed of them has been established, as more or less failures in either the quality of the milk or the flesh will sometimes occur.

In regard to the present status of thoroughbred Short-horns as first-class dairy cows, and the ordinary opinion of the present day that they are not good milkers, the importations of them from England since about the year 1830 have been selected mainly for their flesh-bearing qualities without regard to their dairy products, and these later importations have almost altogether been consigned to our Western grazing States where beef is the main object and the dairy is of no less account. Thus, the Western Short-horns are little sought by dairymen, and the purely dairy breeds are adopted in their place. The "general-purpose" cow is, therefore, a creature of selection rather than of a distinct breed. Even if the dairyman chooses to breed his grade cows to a thoroughbred Short-horn bull, the latter must be descended from a

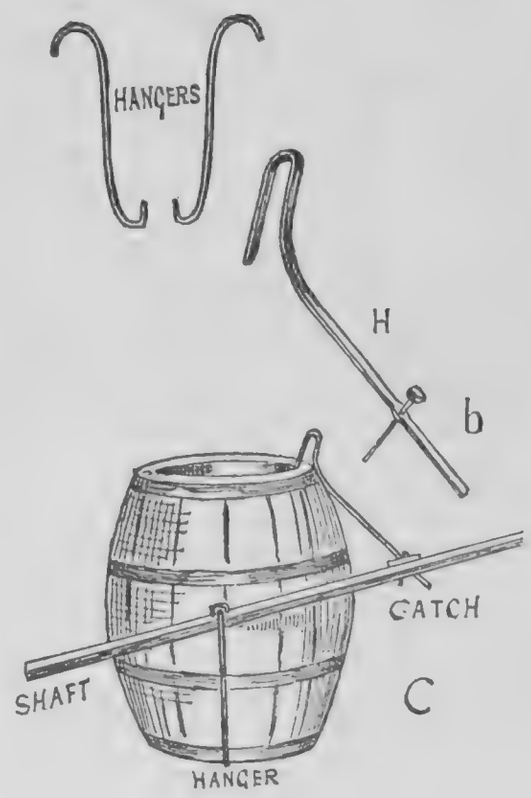

Fig. 214.

line of good milking cows of his own kind or the breeder may be disappointed in the success he looks for; if the bull runs to flesh through his ancestry, his produce may inherit that quality over that of his good-milking dam.

2. I bred from Devon cattle for more than 30 years, and they were, in their purity, more nearly the "general-purpose" animal than any other that I have known as a distinct breed. The cows, as a rule, were superior for the dairy and for beef, at any age, and their meat was of the best quality. They are of medium size, the cows weighing, at full age, 1,000 to 1,200 pounds, and well fed steers at 3½ years weighing from 1,200 to 1,400 pounds, alive. No handsomer or more graceful cattle—pure red in color—can be found, and the farmer who possesses a herd of them has as good "general-purpose" animals as he can find or better, and the same can be said with regard to their high grades.

The Red Polled cows, from what I have seen of them (never having bred them), I consider, next to the Devon, as good general-purpose cows as any others. They are of about equal size, well shaped and for those who object to horns these may take the place of Devons, either pure-blooded or grades.

The distinct dairy breeds, such as the Guernsey, Jersey or Holstein, cannot be called general-purpose cattle, as their purely flesh-taking qualities are not of special consideration, and the choice of either one of them in preference to another may be left to the decision of the dairyman. They cannot be enumerated for "general-purposes."

Niagara County, N. Y.

A GROUP OF JERSEYS.

HAVE you ever seen a more life-like cattle picture than that shown at Fig. 209? The engraving is taken directly from a photograph kindly sent us by our contributor, Mr. W. B. Pratt, of Steuben County, N. Y. It is a beautiful scene. The cows are well grouped and stand exactly as farmers have dozens of times, seen such cows stand in the pasture. It is a peaceful, restful view. The early October frosts have begun to strip the foliage from the trees. Could we paint this picture in colors, the woods would be radiant with the glorious autumn tints. Off to the left is a pretty country village. To the right rise the uplands that stand between this valley and the grape regions bordering on Lake Keuka. It is a picture that does one's eyes good to look upon. As to the value of this herd for the butter dairy, our readers are referred to Mr. Pratt's dairy record for 1888, which may be found on page 36 (January 19) of this volume of the R. N.-Y. While this picture was taken several years ago, and does not fairly represent the present herd, it at least shows the animals from which the present grades are descended. These grades, as the record will show, average nearly 300 pounds of butter per year.

Entomological.

CLEAN CULTURE VERSUS CUT-WORMS.

C. P. GILLETTE.

THE intelligent tiller of the soil knows full

well that it always pays to keep the weeds subdued in field or garden. He will be amply paid in the increased yield of the present crop and also by the lessening of his labors for another year. But there is another reason why weeds should be kept down, that few, perhaps, have noticed and that is to lessen the cut-worm attacks the following season. These worms are very general feeders, eating almost anything that grows out of the ground, not excepting buckwheat, and the more abundant the plant growth the greater will be the liability of injury from these pests. Twenty-two farmers of Iowa have reported to the station the proportion of their crops that have been destroyed this season by cut-worms on land allowed to grow up to weeds last summer. The estimates range from two per cent. to 100 per cent. with an average of 40 per cent. the smallest losses being on land that was plowed late in the fall. Two cases that have come under my observation the present season are worth mentioning. A piece of ground in tomatoes and squashes last year grew up to weeds in Aguust and September. This ground was plowed in the spring and set out to root grafts of apple, plum and cherry. For some time after the leaves should have appeared it was noticed that the buds had, apparently, nearly all dried out and spread open and the grafts themselves seemed to be dying. On examining the ground about these grafts, it was found that cut-worms were present in large numbers and during an evening visit (between nine and 10) the worms were found eating out whatever was left green in the buds. It is doubtful if there would have been a living bud left if vigorous means had not been taken to destroy the worms which were gathered by the quart and killed.

Another piece of ground comprising two or three acres was in potatoes last year and allowed to grow a perfect swamp of weeds in late summer. Last spring the field was again plowed and planted to potatoes. On the second of June I examined this field of potatoes and estimated that 75 per cent. of the hills contained cut-worms and that more than half of the sprouts that had appeared up to that time had been cut off beneath the surface. Other equally striking examples might be given but these will suffice. When enumerating cut-worm remedies we should not forget to mention clean culture.

Ames, Iowa.

NOTES.

I have been worrying in good earnest this season against the striped and cucumber flea beetles. I find that of the many substances tried, ashes and a strong tobacco decoction are the best specifics. Ashes to be effective must be used in great quantities, and in some cases they seemed to injure the plants. The tobacco decoction was even more effective than the ashes, and did no injury to the radishes or potatoes on which it was used. I used for the decoction cheap tobacco dust or waste which I secured at the large factories. I believe this remedy will give excellent satisfaction: I shall try it farther another year.

Many and serious complaints come from fruit-growers regarding injury done to peach trees, which were sprayed with London-purple. I have experimented very fully in this matter. It seems that London-purple is far more injurious than is Paris-green. The latter, used one pound to 100 gallons of water—a mixture at least twice too strong—and twice repeated, did almost no harm; a mixture one-half the strength did no harm at all. The London-purple of the first strength always did some harm and often serious damage. A rain just after the application seems to increase the damage. One pound to 200 gallons of water injures peach, cherry, apple and plum foliage often seriously, especially when repeated. It is much the most injurious when used on the peach. The leaves often fall off. Frequently one application of this weak mixture, would be followed by entire defoliation.

I find that the colored water turned carefully off after the London-purple has all settled, will still kill the foliage. Can it be that the analine is the poisonous substance? Or is it the soluble arsenic? I am now having analyses made to determine this last point. If an arsenic is to be used on the plum and peach, we must use Paris-green, and for the peach this must be very dilute. I should not make it stronger than one pound to 250 gallons of water. PROF. A. J. COOK.

Various.

JERSEYISMS.

Now is the time to begin the annual criticism on feeding off the meadows. Some say it is harmful, and some say it is not. For my part I think it depends altogether on the character of the land. Some fields can be fed, and some cannot.

Tobacco-culture exhausts the soil, and we accordingly lavish great pity on the growers. But,—did you ever think of it?—the injury to the soil caused by tobacco-growing doesn't compare with that caused by peach-growing.

How careless farmers are about lifting! One is apt to try to lift a-third more than a day laborer attempts, and the consequence is a rupture. Sixty per cent. of our farmers are so afflicted, and it is all owing to their own faults.

"What shall I decorate?" asked an insipid city boarder of me. And I showed her the butter-crocks, churn, hen-coop and mowing-machine. "Take your choice," I said. She looked at me softly, and then sighed sadly.

How can the thistle be eradicated? I will tell you: Cultivate it. Try to fertilize a thistle and you kill it. So, cultivate it as you would a rose. The pest loves poor soil, and if you make it rich, you kill it.

Be particular about the horse shoers you patronize, and always employ the same smith. Do not change. A smith gets used to a horse, and horses get accustomed to the handling of a particular man. "The best is none too good."

Never smoke or allow smoking in your barn. If possible, do not employ a hired man who smokes. Never carry a kerosene lamp or lantern into a barn. Instead, use oil—old-fashioned, but safe.

My neighbor Riggs has a mound in his pasture, graced with a board, on which he has painted: "Here lies a red heifer, poisoned with Paris-green by the carelessness of J. D. Riggs. Was worth $40." Riggs says that every time he sees it he is reminded "to be careful."

"Two fifths of the inmates of ——— Asylum are farmers." Well, farming didn't make them insane. Two-thirds of those unfortunates were rendered so by intemperance—drank cider to start with.

Peas planted May 9, bloomed in 31 days; while peas planted July 1, bloomed in 21 days. Same plot of ground, same fertilization, same kind of peas.

Joe Brown has gone into partnership with his son on his farm: "J. Brown & Son." Charley does half of the work, pays half of the expenses, and has half of the profits. Good idea, the boy being 21.

How much are you worth? Impertinent, I know; but really, do you know? Reckon it up. If you are poor, what made you so? Find out, and get rid of the cause. Wasn't it because you "got trusted" so much? That's a bad idea—very bad. JAY ERR SEE

GREAT EXPECTATIONS,—HOW DISAPPOINTED

T. H. HOSKINS, M. D.

A STANDARD old farmer's joke is on the man who said that his pig, when slaughtered, did not weigh as much as he expected; adding: "And I always knew it wouldn't. "Isn't this about the way with the crops of many of us? We think this, or that, or the other field of grass, grain or potatoes, ought to give us such and such a yield; and yet has there not been all the time a sense of doubt, causing that sinking feeling about the pit of the stomach—"epigastrum," we doctors call it—where our business conscience seems to have its head quarters? Oh, how seldom the premium crop we hoped to make materializes to the full in the bay, or the bin! Why is it so? Is it not because we have been hoping for that Will-o-the-Wisp called good-luck, to remedy some of the conscious faults and deficiencies of our work? Did we fit the ground just right, in the best manner? Did we allow enough manure, or fertilizer for a first-rate crop? Was our seed just right? Did we get it in at the right time? Did we tend the crop faithfully? Was our grass ground rich enough to stand that dry time in early June, and had we used seed enough, and was it good enough, in seeding it down?

AGAWAM BLACKBERRY. From a Photograph. Fig. 215.

The longer I live and farm, the more I am convinced that profitable farming must be found in thorough farming; and I know that unsuccessful farming follows bad business judgment quite as often as anything. Losses will result from idleness, carelessness, lack of capital, want of knowledge. All these are factors in the cases we see, where farming plainly does not pay. Yet take them altogether, they do not hurt a farmer so much as the defect of that peculiar thing known as "business sense." With this we shall never expect something from nothing, which is the worst of all the causes of failure on the farm.

Undoubtedly a man may have good luck in farming, as in buying lottery tickets. But woe to the man who puts his trust in what he calls "chance," and especially woe to such farmers. "If scarcely the righteous (i. e., the right-doing,) be saved," how can the farmer whose conscience hounds him with the continual thought that he has not been faithful, that he has not done as well as he knew how, or as he could have done, but has pacified his conscience by the false hope that he may not be obliged to reap as he has sown—how can such a man believe that he can be successful?

To carry on a farm to assured success requires as strict a training, and as faithful adhesion to duty, as to command a ship. Every thing must be foreseen and provided for, and nothing that man can do should be left to chance. It takes a first-class farmer. No wonder, then, so many declare that farming doesn't pay. But it is the best of all businesses for incompetent men—who, if they don't make it pay, survive at farming many years longer than they could hold out in any other way of life.

Here is a great fact that should always put heart into the improving farmer. The world must be fed and clothed, and only the farmer furnishes the wherewithal. The price of food and clothing must forever be based on the cost of production. The farmer who cannot get a living out of the land must give up. Prices therefore must be based upon average farming. Anything better in the way of farming than an average, life-sustaining return, *must give a profit*; and that profit must increase with the efficiency of the work. Or, in other words, the more than average farmer must make *some* profit; and if he will keep on improving his farming, and investing his profits wisely, his farming is sure to pay. The proofs of this are to be seen in every county in America.

Dairy Husbandry.

DAIRY DOTS.

MILK FOR HENS.—I don't "know," but I think that if skimmed milk is fed to the hens instead of the pigs it will yield a greater profit. Our hens get nothing to drink but milk, and they lay right straight along. One advantage in butter over milk dairying is that the skimmed-milk and buttermilk are left for use on the farm. Another advantage is that in selling butter you carry off none of the farm's fertility, whereas in selling milk you do. Still another advantage is that you do not have to go to market so often. Horses and wagons cost money; a neighbor of mine sold milk and kept two wagons; as he put it, "he had one wagon on the road and one at the shop."

MAKE GOOD BUTTER.—But we can't all make good butter; if we did, it wouldn't pay; as it is only good butter that pays, the general run of farm dairy butter must be sold at a loss in summer. Why is it that so many farmers breed their cows to come in in the spring? The result is a glut in the market and low prices. Some say that winter calves do not make as good cows as spring calves; but they do, and, besides, there is more time to attend to them and they are not bothered with flies. Then when grass comes they are old enough to get a good part of their living from it.

FEEDING CALVES.—How much milk should a calf have? My practice is to feed four quarts a day in two feeds till the calf is from 10 days to two weeks old, then gradually increase the ration. For the first week it gets new milk, by the end of the second it gets all skimmed-milk with linseed or flax-seed meal to supply the loss of cream. The calf is weaned when three days old, (if the cow is a very rich milker, when one) and is taught to drink by putting two fingers in its mouth. This is better than to put only one finger in, as by spreading the fingers a little the calf can more readily suck up the milk. When the calf is a week old hang up a bunch of the best clover hay within its reach; it will soon learn to eat it and it is surprising how much it will eat.

THE "SCOURS."—When a calf scours it is generally the owner's fault; he has given it too much or too rich feed. I wouldn't doctor, but diet it; one may let it go without one meal, and then if it is three or four weeks old, begin with the original ration of two quarts at a feed, watching the calf closely as an increase is made in the quantity. If you had watched it as closely before it got the scours it would never have had them.

WHEN TO BREED HEIFERS.—I like to have them drop their first calves when they are 22 to 23 months old. They may make larger cows if not bred so young; but I don't want a big cow for butter; mine grow too big even when bred young. Even for milk we don't need a "big" cow; size alone doesn't govern production and we have to consider the cost of feeding the extra weight. It is what we get from the cow daily, not what we get for her when we are done milking her, that makes our profit. If I were selling milk and

getting paid according to the per cent. of solids it contained, I would not want any larger cows than I would for butter making. A small cow with the right kind of machinery in her can get all the milk solids out of a given amount of feed as well as a big cow. But if you have good, big cows and they give you a fair profit, keep them, but breed them to the smallest good dairy bull you can find and if the result is a more concentrated cow I think you are the gainer. A. L. CROSBY.

Catonsville, Md.

WHENCE COMES THE COLOR OF BUTTER.

BUCEPHALUS BROWN.

THE editor of the Maine Farmer, who is also secretary of the Maine Board of Agriculture, and a practical dairyman and fruit-grower, (known to be successful at both), complains of being made "tired to read the many efforts of the know-nothing suburban at enlightening the dairyman on methods and practices in his work." This is in reference to the following from the RURAL NEW-YORKER.

"There is a much better way of making good-looking butter than by adding questionable ingredients to it, and it is a much more profitable way. It is to put the color into the feed, by feeding sugar-beets, carrots, parsnips or squash, notably the last, with a ration of corn meal and bran, in addition to clover hay and corn fodder. By these means one can in winter make butter as sweet and attractive as in June."

To which the somewhat hasty Down Easter responds by the dogmatic assertion that "it is *green* food, (not yellow), that gives the golden hue to butter, and the color goes up or down in accordance with its presence or absence."

It would be very interesting if editor Gilbert, restraining his wrath, had told us how he knows his statement to be true. The time is fast going by for dogmatic assertion, unaccompanied by proof, to be accepted as truth. Even a suburban farmer may be allowed to experiment in feeding his cows for color in their butter, and to record the result for the information of others; and however far-back another farmer may be farming, that fact alone is not sufficient to justify so much scorn.

It is quite plain that neither of the two statements necessarily invalidates the other; and it is sure that even if both were true, (as probably the majority of farmers think) they do not exhaust the truth on this subject.

I have kept cows, and milked them, for 40 years, and have always desired to have the butter of a good, natural yellow. It is a mortification to have to dye butter in order to have it sell, or look right on the table. But I have had to do it; and so, no doubt, has our Maine friend. Nevertheless, I have had cows which would make yellow butter without any green food. Also, I have had cows that would make only a very pale, yellow butter on the best of grass. As to the effect of vegetable colors, yellow or green, upon the color of butter, it has often proved very uncertain. In a chemical point of view, there is not so much difference between them as necessarily to settle the point that yellow food will not highten the color of butter in any case. My experience leads me to believe that it sometimes will; but it has also proved that it often fails.

The dominating fact in the case is, that something in the constitution of the cow herself has more to do with the intensity of the yellow in her butter than any feed; else why do we look for the yellow skin, and why do the yellow-skinned Jerseys and Guernseys give us so much high-colored butter, irrespective of feed? And again, why will a cow give a higher-colored butter on the same feed after than before calving?

Since winter dairying has become common, and the cows are made to come in late in the season, there has been much less difficulty in getting a good natural color in winter butter. The assumption that all the color of the intermuscular fat, the skin and the butter fat of the cow, is derived from the chlorophyl of the once green plants upon which cows are fed in winter, is too lacking in proof, and is confronted by too many plain exceptions to be set up as absolute truth. Both corn-meal and roots when liberally fed, have often appeared to deepen the color of the butter. I do not know of any recorded experiments carried on with accuracy to show that butter will be colorless when no food containing green chlorophyl is fed. Here is a chance for our experiment stations. Meantime, perhaps, we had all better avoid positive statements on the subject.

The Poultry Yard.

AN INTERESTING CHICKEN EXPERIMENT.

I WILL give RURAL readers the benefit of my loss and experience in rearing chickens by artificial heat. I bought the buildings in a vacated lumber camp and stocked a large boarding-house with 100 Plymouth Rocks in the fall. A large stove protected by wire netting stood in the middle of the room. Aside from the grain ration, I put away several barrels of shells and forest nuts—mostly acorns. Wild turkeys and pigeons eat acorns, and domestic poultry relish nuts after they are crushed in the bone-mill. To save time such nuts can be raked and shoveled. Scratching over the leaves gives the fowls the desired exercise in winter. Early broilers were my object, so I canvassed the neighborhood for sitting hens in December, the chicks to be removed as soon as hatched, to the loft over the stove which was provided with several lath heat registers in the hennery. The mother hens were confined in coops. The chicks had the run of the loft floor, well lighted by windows. The laying hens were on the ground floor. By February 1st I had 600 emaciated chicks which began to die by the dozen from no perceptible disease. I had a good supply of onions and cabbages so much coveted by fowls in winter. I fed them rabbit meat; still they died. Several people of culture, booked high in poultry lore, gave the cause of the mortality among them up as an enigma, when asked for a remedy, and said, "You can't raise young chicks in that way now. It's out of season and contrary to Nature." I placed a thermometer on the first floor. It registered a little above the freezing point. In reviewing the past, when the school teacher placed water on the school stove to supply moisture to the room, it came to me that I was kiln-drying the chicks; that moisture was wanted in that atmosphere which was drier than the zero air outside. As soon as the stove generated steam those chicks huddled over the registers to receive it. They also began to pay attention to their toilet, pluming themselves ,and they grew as they might have done in "balmy June." I believe that caged birds and infant children suffer in winter from fever heat.

Indianola, Ill. L.

Educational.

A STONE-MASON IN THE GARDEN.

OLIVER HOWARD.

HERE it is midsummer. Everybody is busy, and there is more work than all hands can accomplish. I chanced to hear Florence say that a man at the back door was asking for something to eat. Presently I said:

"Where is that hungry man?"

"I fed him at the door and he is gone. There he goes toward town."

I called after him, wondering what kind of a man this could be, who was willing to beg my bread when there were 17 mouths in our house, counting children, workmen and visitors, that must be supplied. "Here, sir! Do you want work?" The man walked slowly back—a strong-looking man, perhaps prematurely aged. He had not asked for work.

"Go and work in the garden this afternoon and I will give you 50 cents and your supper."

"I'll do it," he said. "Half a dollar would help me a good deal as I am fixed now."

He had been a soldier, was 53 years of age, and was a stone-mason by trade. He had held a claim in Kansas and had traveled through several cities seeking for work. He stayed with us a few days; a man who had roved over the world a great deal; an intelligent, quiet man to all appearances, strong and willing. As a "comrade," I did my best to find him a place on some stone-work at the new foundry; and at last he drifted away, after purchasing a new hat.

He was a very candid sort of a man, and as he took a good hoe in hand he said: "I shall not be much of a hand in the garden. I have never been taught. I don't know anything but just my trade." It was true. If I worked with as little skill in my garden as did the stone-mason, I would certainly some day be begging bread, too, or worse. The eye that had been trained to hew stones to a line, and to lay the foundations of great buildings securely, could see no difference between a red-root weed and a potato plant. I pointed out the slight difference in color, and the difference in the form of the leaf, but he couldn't "catch on." He tried hard to please me, and I let him alone, but yesterday in weeding after him, we were able to discern "the stone-mason's row" all the time.

Now I have a suspicion that there was a fundamental error in my stone-mason's education. He had not been taught to observe and discriminate. Prof. Agassiz would not have confounded a useless weed with a noble esculent. His trained eye would have "caught on" at once. May it not have been that the mason has this fatal lack of discrimination in his own trade, and so roams from city to city, working a few days here and there, and then pushed gently out of the way to give place to a more intelligent workman?

I trust I do not seem to be belittling the comrade. I suspect he did far better in my garden than I could possibly do with his plummet and trowel. But look at it, you who wish well to the babes in a million cradles! What about this modern narrowing down of human activities and observation? In our shoe manufactories one laborer does one small thing toward making a shoe, and that is all. No man makes the finished article. My stone-mason told me that something very similar was going on in his trade.

In all trades the tendency is to concentrate effort on some one detail, to educate one faculty, one set of muscles. Pretty soon there comes a great invention or a business stagnation and numberless helpless crafts lay all along the shores of the ocean of labor. We educate a man so that he can make a pin-head better than any other man in the world. What then? Possibly next year some inventor will give us an implement that will completely supersede the pin or human labor in making it. What then is to become of our famous pin-head maker?

The only answer I can make is this: Since competition is bound to become sharper and sharper, our boys and girls must be educated broader and broader as the field of labor narrows. If the labor that sustains me calls but for the education of one set of muscles, health, happiness, common sense demand that the gymnasium or some substitute shall train my other muscles. With trained muscles one may quickly and easily adapt himself to changes of occupation.

Most of us having eyes see not, and having ears hear not. Take a child, and what does he see in the vegetable kingdom? Most children see almost nothing. But let a botanist train the same unseeing child, and what a change! A whole new world opens to him. A thousand marvels are revealed where before he absolutely saw nothing. He would know a red-root from a potato. And the long and short of the lesson that my indigent stone-mason taught me is this: broader education for muscle and brain.

Weld County, Col

Field Crops.

POTATOES ARE ROTTING.

DR. BYRON D. HALSTEAD.

WE have had an unusually wet July, and with the thermometer at only a moderate hight during the same time the most favorable conditions have obtained for the development of the many forms of blight, mildew, rot, etc., which prey upon the farm and garden crops. At the time of writing, August 7th, the vineyards in many places insure no crop for this season; the pear orchards are frequently without foliage enough to protect the starved fruit from the sun, and, worst of all, the potato crop is certain to be small and of poor quality.

The low form of plant which has been preying upon the potato and generally known by its effects as the rot, is a very rapid grower and does its destructive work without giving much warning. This may be in part due to the nature of the mildew, but, perhaps, more to the particularly favorable conditions furnished by the texture of this plant and its nearness to the soil. In a rank-growing potato field the herbage or "tops" make a thick succulent mass, each portion of which whether it be leaf or branch is easily penetrated by the threads of the fungus. This mildew heretofore has made sad inroads in the potato crop, and invariably the seasons of much rot have been years of excessive moisture. That the plant causing the decay of the vines and tubers is fond of moisture proves no exception to the general rule for this class of plants This is especially true when the rains are coupled with much cloudiness and a moderate temperature. Those days that are spoken of as "close" are the ones in which the bread molds in the pantry, the shoes in the closet and the living plants in the garden. What other conditions favor the development of the rot it is not so easy to state. Some think that an abundance of coarse manure or like decaying substance in the soil induces the decay.

(*Continued on Page* 563.)

Farm Economy.

A HOME-MADE HARROW.

I SEND—see Fig. 210—a plan of a home-made harrow like one I have used for several years. It should be used after other harrows to make the ground fine and smooth Take seven pieces of board four feet long, five inches wide and one inch thick; fasten them strongly together with nails; then bore holes three inches apart in the cross-pieces for the large eight-inch nails so that they will go through snugly and stay with the heads one inch above the boards. Then they can be driven down if desired at any time. Put a chain or any fastening at one corner as the harrow should be drawn cornerwise. Two can be hinged together if desired. The expense will be from 75 cents to $1 if the implement be made at home. There will be 15 large nails in each cross-piece—60 in all. T. A. J.

Binghamton, N. Y.

TO REMOVE A CORK.

AT Fig. 211 is shown a simple method of extracting a cork from inside a bottle with a string. It may not be new to some RURAL readers, but after proving its simplicity, convenience, and effectiveness, I could not refrain from sending it to the paper.

A FRIEND.

SOME LABOR-SAVING APPLIANCES IN HOG FEEDING.

SCOOP FOR DIPPING SLOP FROM BARREL.—This is made from an old gallon paint can. The handle is of wood and nailed on, nails being driven through the can into the wood, and stayed by a band of hoop iron as shown in Fig. 212 in the upper part of the cut. On a cold, frosty morning it is no fun to lift the bale of the bucket from the rim. Two small blocks of wood grooved to fit the bale and then wired on as shown in Fig. 212, in the lower part of the cut, will save much trouble.

TRUCK FOR WHEELING SLOP.—Have an axle bent to fit half way around the barrel. Bolt on shafts and a cross-piece, as shown at Fig. 213. Two inches beyond the axle fasten on the shafts movable hangers (h, h) Fig. 214. The hangers should be a little over half the length of the barrel, with the lower ends sharply turned up to catch under the barrel. They may be fastened on by curving the upper ends over the shafts and driving over them a staple loosely enough to allow play, to keep them in place. The barrel in which the slot is cut should be placed on a block five or six inches high with a part of the bottom projecting on each side of the block to allow the hangers to take hold. Raise the shafts up. This lowers the hangers. With one foot and the catch in one hand shove the hangers under the projecting bottom of the barrel so that when the shafts are lowered the hangers will lift the barrel, place the bent part of the catch over the top edge of the barrel and fasten the other end to the cross-piece with a pin as shown in Fig. 214. Then wheel the barrel to the pig-pen; have another block of the same size, and reverse the operation. It will save emptying slop if two barrels are used. A swinging leg should be placed on the other end of the shaft away from the handles, with a string attached to the handle so that it can be drawn out of the way when the barrel is in motion.

Catonsville, Md. P. B. C.

Everywhere.

RURAL SPECIAL REPORTS.

Colorado.

GREELEY, Weld County.—As yet we have no very large markets for our abundant truck, except Denver, and that is so well supplied that we cannot ship thither. Cheyenne used to be a good market; but I suspect the good people of that berg used to pay higher for "garden sass" than any people on the continent. Now the truck gardeners of northern Colorado just fight for the market. One man I know, in his eagerness to hold the trade, ships large consignments of vegetables, saying to the dealers: "Take this; sell all

you can. Charge me up with what you are obliged to throw away." And a great deal is thrown away which has already cost a goodly expressage. This is the beginning of the end of such men. Shortly the mortgage will arise and, like Banquo's ghost, refuse to down. Whoever goes into the business after the plan of the fabled roasted pig which had a knife and fork stuck in its back and went about squealing: "Come eat me," will doubtless one day be eaten. What else can we expect of dealers, who are thus daily led into temptation. There are men who make their appearance on the streets of certain cities selling here and there bunched turnips, beets, radishes, etc., at *ten cents per dozen bunches.* What a slaughter of the innocents! The season is just a grand one for all vegetation, which includes weeds. Our market gardeners could not this season endure to hear the eloquent Patrick Henry thus declaiming:

"Gentlemen may cry Peas! Peas! but there is no peas."

I suppose I have 60 to 80 bushels of various kinds, and no market for them. The agricultural outlook in this vicinity is so favorable that we are prepared to hear an outcry that produce brings nothing. I wish we could raise fruit to advantage, but thus far, we have not been greatly encouraged, except with small fruits. O. H.

Indiana.

DE SOTO, Delaware County.—I have been engaged in small fruit growing here for the last five years, but this has been the poorest season in the whole five to make money. Prices have ruled very low on the account of such wonderful crops. The average price for berries of all kinds has been about $2 per bushel. I think the Snyder Blackberry is the most prolific of all the kinds that I have. The Wilson Junior is no good with me. T. M. G.

PENDLETON, Madison County, August 3.—Wheat is variable in yield and quality. Some fields produced 25 bushels per acre; others five to 10. The quality varies with the yield. The best yield is generally of the best quality, and the best farmer usually has the best wheat. The practice of thrashing from the shock, delivering the grain at the ware-house, and selling at once, is becoming general, in this part of the State. It saves time, labor, waste, and shrinkage. The price is from 40 to 70 cents per bushel. Oats are good, but hard to harvest, as they have been prostrated by rain and wind. Local price 18 to 20 cents. Corn is good for so wet a season. It has not been as well cultivated as usual. Many fields are verdant with weeds and grass. A larger amount than usual of old corn is held by farmers.

Indiana girls will have a good chance to win premiums in the potato contest, as the yield is large. S. W. H.

New Jersey.

CRANFORD, Union County, August 12.—In common with other sections, we have been blessed (?) with an extra amount of rain, but the weather now is clear and cool. The principal occupations of farmers in this section are milk-dairying and truck-farming. The rains have kept pastures in prime condition, so that cows have held out well with their milk, but the ground has been too wet to work, and much of the truck is overgrown with weeds, and is in very poor condition. Much hay was secured in very poor order. Oats and rye are the only grain crops raised; the latter was considerably below an average crop, and the former was nearly ruined by the wet weather. Potatoes are rotting badly, especially on low and heavy land. There are a great many of the "farmin'-don't-pay" farmers here. The land needs draining; it needs fertilizing, and should have a few brains applied to it. The villages are occupied by people who do business in New York, and many of the land owners think it will be a question of but a few years when the country will all be required for such residences, and they can dispose of their land at fabulous prices. There is a surplus of garden-truck, but first-class fruits are scarce, and sell at prices that will pay handsomely for the extra care needed to produce them. Eggs are worth 30 cents per dozen, but it is too much trouble "to fuss with hens." The farmer who will not "fuss" with these smaller matters, is the one who generally lets the larger ones go at loose ends, and says that "farmin' don't pay." H. V.

Vermont.

WHITING, Addison County, August 10.—We are having a very unfavorable haying and harvest season, and much of both hay and grain in this section will be entirely ruined. Such an excessive rainfall, such a succession of "cloud-bursts," were never before known in this section. We have a rank growth of all kinds of vegetation. Corn on the uplands looks well, while rust has injured nearly all the small grains, and the rot is already making its appearance in potato fields. Rust has also ruined many fields of onions, which are raised quite extensively here. The agricultural outlook with us is anything but favorable. F. D. D.

THE FARMERS' CLUB

ANSWERS TO CORRESPONDENTS

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see if it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

ARSENIC IN POTATOES.

A. H. B., Mansfield, Mass.—Can the continued use of Paris-green as a means of killing the potato beetle possibly affect the quality of the tubers? Some farmers about here attribute the bitter taste discovered in potatoes for the past few years to the use of the "green."

ANSWERED BY DR. E. H. JENKINS.

It has been abundantly proved by examination of the tubers that potatoes do not take up the smallest trace of arsenic even when Paris-green is used very abundantly for poisoning potato bugs. The bitterness spoken of must have come from some other source.

New Haven, Conn.

FROM DR. PETER COLLIER.

I have no information going to show any evil results following the application of Paris-green as usually made for killing the potato beetle. I question whether the bitter taste noticed by your correspondent in the tubers proceeds from such cause. But apropos to this matter, my attention has recently been called to very injurious results from the application of London-purple to fruit trees in this vicinity, and I am inclined to believe that the observation merits careful attention, since the two poisons would, I think, affect vegetation very differently.

FROM DR. HENRY STEWART.

The question as to the possibility of any injurious effect upon the soil or the tubers from the use of Paris-green to destroy the striped beetles which do so much injury to the potato crop, came up for discussion five or six years ago, and was then considered settled in the negative. No injury was believed by theory or hypothesis, or perceived by observation and experiment in any form or manner. But since then the use of arsenical poisons for the destruction of predaceous insects has increased enormously, and in such a manner as to favor the spread of arsenical vapors in the atmosphere, the question may well be extended, and in reviewing the experience of the past years in regard to the possibility of injury to the potato tubers, the possibility of danger in another way might be usefully discussed, or at least suggested for discussion. As regards potatoes, there can be no question, I think, of their perfect safety and inviolability from the Paris-green. Plants never take any solid matter into their circulation by their leaves, either in its solid condition as the most impalpable powder or even in a state of solution. The leaves do not even take in water through their own agency; it is contrary to the very nature of the leaves, which are beautifully varnished with a coating of wax and furnished with fine hairs for the purpose of resisting water and shedding it as it may fall upon them. The bright drops of dew or rain which may be seen upon the leaves are instances of their repellant disposition and power, and we may consequently dismiss from our minds any fear of danger from this source, and rest assured that the plants will not absorb any of the poison through their leaves. But it is well known that plants take up soluble matter, that is in solution in the water of the soil by their roots, and it is believed by many competent, intelligent persons that they do not possess the power or instinct of selection whereby they might choose the food which is nutritious and necessary and refuse that which is unnecessary or hurtful. Almost every inorganic element in the soil can be found in plants not only those which are necessary to their growth, but many which are not necessary. Traces of the metals have been found in the ashes of plants, as of iron, lead, copper, silver, lithium, arsenic and even gold and the rarer metals have been perceived in the spectrum analyses of vegetables. This being so, we cannot doubt that any substance that can be dissolved in water—and water is a universal solvent—must be absorbed to some extent by the roots of plants. The absorption of food from the soil is a mechanical process, the digestion and assimilation are chemical processes, hence there can be no selection by the roots of plants (hypothetically considered) of such substances only in the soil as are useful and necessary for the plants, and as practically studied by experiment this supposition has been completely confirmed, for by watering plants with solutions of certain injurious substances, the plants have become diseased or have been killed outright. In practice this has been proved by experience innumerable times. An over-dose of chloride of potash or of common salt; a very small dose of sulphate of iron or of sulphuric acid and the alkali (soda) of the Western plains, as is very well known, will kill the useful plants, sparing only a few which are naturally capable of resisting their injurious effects or even of assimilating them.

But arsenic and copper do not exist in the soil except very rarely and where they are found in a soluble condition to any extent the soil is barren because the vegetation is killed by them. They are only sparingly soluble, and cases are very rare where injurious results from their presence have been noticed. As to Paris-green, the arsenic and copper contained in this compound, are practically insoluble and the small quantity used of this insoluble substance would leave the merest trace of it—a quantity too small for weighing in the most delicate chemical analysis—in an acre of soil. Thus I think we may equally discharge from our minds any fear of danger to the tubers, or through them to those who consume them. But I would like to suggest to those readers of the RURAL who are interested, the question whether the prevailing practice of spraying fruit trees to destroy the apple moths and leaf-eating insects, may not be a source of danger through the well known easy sublimation or evaporation of arsenic. It has been proved beyond question that Paris-green and other arsenical compounds used for coloring wall papers in dwelling-houses have produced disease in persons through breathing the poisonous vapors. The arsenic contained in the color of the wall paper of one sleeping-room might not amount to more than one drachm or even less and the portion volatilized in the air is only a small part of this, yet it has had a most serious effect in numerous cases. An orchard may have a pound of Paris-green sprayed over it and this will contain nearly 12 ounces of arsenious acid, of which undoubtedly a large portion will be volatilized and mix with the atmosphere during the warm summer months. Is there not a serious danger to health lurking in this unsuspected source? Some of the symptoms of the prevalent summer complaint and of certain fevers may easily be mistaken for those of arsenical poisoning, such as pains in the bowels, nausea, vomiting, diarrhea, clammy skin, cold sweats, hectic fever, sense of weariness and mental depression, and it may be that these symptoms are due to the effects of the arsenic in cases in which the causes are too obscure to be easily determined.

NON-CONDUCTORS OF HEAT IN WALLS OF BUILDINGS.

R. M. C., Chiswold, Del.—I am building a house for the winter storage of sweet potatoes. It will be weather-boarded with inch hemlock, and covered with tarred-felt roofing, and I propose having a four-inch or eight-inch wall, either filled with sawdust, or without filling, if it is safe to have such a one. Is it a settled fact that a wall with a dead-air space in it is as safe a protection against frost as one that's filled?

ANS.—A dead-air space is not an effective non-conductor of heat. The radiation of heat is more easy and rapid through still air than it is through porous substances which contain air. Dry sawdust is about one-third more effective than an empty air space. The best non-conductor is a substance which has the largest number of air spaces of the smallest size. Hair, felt and the so-called mineral wool, which is really fine fibrous glass, are the best non-conductors reaching an efficiency of about 80 per cent. Fine charcoal comes next with an efficiency of about 70 per cent.; then dry sawdust is next with about 60 per cent., and an air space is the last of all with an efficiency of about 45 per cent. But air spaces differ very considerably in efficiency with the various materials of which the walls are constructed. As the material is more absorbent of heat the resistance of the air is lessened. A mere space between common boards is the least effective of all, but if the boards were made air-tight and were painted a light color or covered with smooth bright reflective metal, the efficiency would be the highest; so that practically ordinary board walls not air-tight, with an air space between them, would be but little better than a mere doubled board wall, with paper between the boards. Tarred roofing well lapped and fastened would be a considerable help, but it offers a poor resistance to heat on account of its color; all black substances absorb heat more rapidly than light-colored ones. The best sweet potato houses are provided with stoves for use in dangerously cold weather.

THE KEROSENE EMULSION.

E. H. C., Mattsville, Ind.—What is the latest way of making the kerosene emulsion, and for the destruction of what insects is it especially adapted?

ANSWERED BY PROFESSOR A. J. COOK.

I find that soap is best to use to make or form a permanent mixture of kerosene and water. Every one knows that oil and water will not mix unless compelled to do so. The object of the soap is to compel this mixture so that we can dilute kerosene oil at-pleasure. I use one quart of soft-soap or one-fourth of a pound of hard soap—whale-oil preferred—to one quart of water and one pint of kerosene oil. If desired, we may use larger quantities in the same proportion. I now stir violently till all the ingredients are permanently mixed. I accomplish this by pumping with a force pump, throwing the liquid violently back into the vessel from which it is drawn. After the mixture has become permanent we can dilute it with water to any extent. I use one of kerosene to 15 of all else. Thus 15 gallons of liquid ready to use contain one gallon of kerosene oil. With this strength it is effective, and never injures foliage.

While I find this a specific against many insects, I think it most valuable for destroying plant and bark lice. To use it with the best effect, it should be thrown violently on to the plants by use of a force-pump. This insures contact with all the insects, and as it is contact that destroys this is very important. I have never failed to destroy plant-lice, or the eggs of the same just before they hatch in spring by use of this valuable insecticide.

ACTINIDIA.

F. G. B., Gratiot, Wis.—I was very much interested in the Actinidia polygama, after reading the notes on it in a late RURAL and would like to learn some more concerning it. 1. How long would it take it to cover an arbor or trellis to make shade for about 50 colonies of bees? 2. Is it a honey-producing plant? 3. Where can I get the vines? How far apart and at what time of the year should they be set? 4. Does the American Linden or Basswood grow from cuttings? If it does at what time of the year should they be set? What is the best method of propagating it?

ANS.—1. The third year the vine would cover an arbor say 10 by 10 feet. After that it grows with great rapidity. As the R. N.-Y. specimen has been permitted to grow whithersoever it would, its growth has been upwards at the expense of lateral growth no doubt. We can not definitely answer this question. 2. Bees were not noticed among the flowers. 3. Our vine came from Ellwanger & Barry of Rochester, N. Y. 4. We do not think it does, since the usual plan adopted by nurserymen is to layer the branches in June. It may be raised from seed sown as soon as ripe. They will sprout the next spring. As told in last week's issue of the RURAL it appears that a mistake has been made with regard to the varietal name of this vine. That to which the name Actinidia polygama, has been given, is in reality, it seems, A. arguta, and *vice versa.*

LIQUID MANURE.

S. P. Q., New York City.—My method of making liquid manure is as follows: I put horse droppings direct from the stable into a barrel, pour water upon them and let the mass stand for a few days. Into another 40-gallon barrel I put 25 gallons of water, draw the liquid off from another barrel and fill this one up with it. To do this takes 12 gallons. I add one pound of nitrate of soda. I use the mixture for forcing the growth of the mammoth pumpkins I am growing, applying six gallons to a hill at a time, repeating the application twice a week. Can the RURAL suggest any improvement?

ANS.—You do not state what quantity of horse droppings you steep in the barrel. But supposing you use two-thirds of a bushel of droppings to 40 gallons of water, and to this add also a pound of nitrate of soda, and of this liquid give 12 gallons a week to each hill

Miscellaneous Advertising.

"Herbrand" Fifth Wheel for Buggies.

of squashes, and continue this fertilizing for six weeks, to each hill would be given 1½ bushel of horse droppings, two pounds of nitrate of soda and 72 gallons of water. This we should regard as extraordinary liberality. As so much depends upon your land, the moisture already in the ground and the vigor of the plants, the strength and quantity of the liquid manure to be applied have to be governed accordingly.

SHADE FOR BEES.

C. T. S., Swanton, 'Md.—Remembering that public sentiment is mostly manufactured by the manufacturers of bee-hives, is it best to keep one's bees in a building, and would the RURAL use a corner of the barn?

ANS.—It is not wise to keep bees in a building at all. The building does no good, and it is easier to handle the bees when away from any building, shed, etc. If it is desired to shade the bees, use a grove trimmed high or an apple tree. If no trees are at hand, a board can be used for shade. This should be nailed to cleats so as to be held three inches above the hive. This shade board should be eight or 10 inches larger each way than the hive. If the hives are painted white, shade is not very necessary though, even with white hives bees may sometimes do better in shade or with a shade board.

Miscellaneous.

S. C., Vernon, Vt.—The Orange Judd Co. of this city publish a book on fish culture by Seth Green.

(*Name Lost*).—The peculiar-looking insect is really a spider known as Gasteracantha spinosa, so identified by L. O. Howard, Acting United States Entomologist.

C. T. S., Swanton, Md.—Considering the additional risk of fire, etc., and the cost of power at two places, is it, or is it not best to have one's work-shop in the barn?

ANS.—We shall have to ask our readers to give their opinions regarding this matter. At the R. N.-Y. farm the shop is arranged over the carriage room which is a part of the barn.

J. J., Toronto, Can.—1. How early can I take up red raspberries of this year's growth and be successful in planting and growing them? 2. Does it injure red raspberries to cut the young wood back after they have been planted in the fall? If not, how near to the ground should the cutting be done? 3. Can blackberries be safely planted in the fall? 4. Can Norway Spruces be planted early in the fall?

ANS.—1. Now. 2. Better let the wood mature. This will be the bearing wood next year. 3. Yes, if you mulch them. 4. No. You should wait until spring.

G. H. F., Southampton, L. I.—How is cream raised so as to be thick and solid in summer? I am using the Channel Can Creamery with plenty of ice; but my New York customers say that it is not as solid as that sold in the city. What would a small centrifugal cream separator fit for a dairy of 15 cows, cost?

ANS.—The Howell Cream Company which supplies a good portion of the cream used in the city, informs us that it sells four grades of cream, the quality being determined by the number of pounds of butter that can be made from a can of cream. Extracted cream, or that from milk that has been run through a separator is preferred. Of course, the concern uses large and expensive machinery. The De Laval Company, of Philadelphia, Pa., make a hand separator which is used by some dairymen. It costs about $125.

DISCUSSION.

POINTS IN PEACH CULTURE, ELI MINCH, SHILOH, N. J.—I have received so many inquiries in regard to a note of mine which appeared in the RURAL for July 27, on the use of potash in peach culture, that I am compelled to beg space for a reply. Potash is not the only desideratum in peach culture. I presume the peach orchard to be planted in a dry, well-drained soil that admits of no standing water, and in a location as free as possible from early and late frosts—in fact in a good peach soil. The yellows as described by the best writers may be produced by any of the following plans, and more surely so when they are—as they often are—all combined. In all such cases I will at once say that potash will not supply the loss of other needed conditions for health and longevity. The drawbacks that potash cannot compensate for are: First, weakly trees of low vitality. These may be large trees of weak roots, or overgrown trees of weak, porous wood. For vitality I always select a small tree with an abundance of small, fibrous roots. Second, shallow planting, carelessly done, the roots all crowded together in a small hole, the dirt carelessly thrown in and left loose. Trees should be set rather deep in all proper peach soils (on wet soils deep planting will be ruinous), say three inches deeper than they grew in the nursery, and always on land deeply plowed—say seven or eight inches—and also sub-soiled if possible. The object is to get a deep-rooting tree, to secure it from the effects of dry weather, from injury by any subsequent deep culture, and from being blown over by high winds.

We should form strong bodies to secure a permanent hold on the soil by allowing the branches to start low, say, a foot or so from the ground, making them start upright by judicious pruning and then we can cultivate them much more closely than if the bodies are formed four or five feet high, for in that case the branches always droop, and close culture is impossible. I always permit all buds to grow the first year of planting. A tree in this condition looks unsightly, but makes a strong, robust body: often it will be in the fall an inch and a half in diameter and possibly only four or five feet high. These trees are so bushy that they push an enormous amount of roots, and firmly fix themselves in the soil. The second year they are pruned to a single stem and an extremely strong and healthy growth follows. Three or four branches are allowed to grow the second year, all upright.

Culture is always thorough and deep the first year to cause deep rooting; each year afterwards it grows more shallow until only the surface is loosened. Other crops should never be planted in a peach orchard. They attract the moisture and sustenance from the tree. If one intends to stick to farming he had better drop peach culture. Under the treatment I recommend, the trees will grow luxuriantly and will require heading back each year, or they will soon outgrow all reasonable bounds and form long limbs which will droop with the weight of leaves and fruit. The bending will cause the rupture of the wood cells and a growth of small, wiry shoots will follow, or the yellows will appear.

We now come to potash and soil exhaustion. All soils do not need potash, though most do. I hold that in all soils where potash is needed the yellows will always appear unless it is freely used. The three great needs of the peach are phosphoric acid, potash and a small amount of nitrogen. A large application of nitrogen causes late growth and winter-killing. In my own case I use, before the trees are planted, 1,000 pounds of bone-dust per acre deeply plowed under before the trees are set. Then I annually broadcast 1,000 pounds of kainit per acre. Farther inland the cost of kainit is greater, and the use of muriate of potash and salt is to be preferred. I exhibited at the American Pomological Society's meeting at Boston, Mass., September, 1887, a peach limb three years old over 15 feet long and I had left on the tree five equally long. Such large growth is not desirable. This has all been done on land where, without potash, the yellows take the trees before bearing.

PRODUCTS AND PRICES.

AN ILLINOIS FARM, PLEASANT VALLEY, ILL.—I was much interested in those reports of profitable Jersey farms. Farmers in New Jersey have a great advantage over us in being near an almost unlimited market, thus securing better prices with less expense for railroad freight. The West can never drive them from the New York market on any bulky commodity as long as freight charges remain as at present. Our local markets are the neighboring towns. The nearest railroad town with 500 inhabitants is eight miles distant. The next is 12 miles off, with 2,500 population. Chicago is 135 miles away. There is, therefore, no chance for us to compete with Jerseymen in selling small fruits, and potatoes are seldom high enough in price to pay for raising them in large quantities, as we can haul but two loads of 25 bushels each per day to the railroad. This farm consists of 80 acres of fairly good, tillable land; 40 acres of good creek and marsh pasture, and 80 acres of rough, bushy and stony hill pasture. The stock kept are three work horses, three colts, 10 cows, 25 calves and yearlings and 20 two-year-old steers and the offspring of 10 breeding sows. The sows are full-blood Poland-Chinas and the pigs are sold for breeding purposes to neighboring farmers. Two litters per year are raised and the sows are kept as long as they behave well and bring profit. Any faulty ones not sold for breeders are fattened and put on the market. The amount of land under different crops averages about as follows: 20 acres in corn; 15 in oats; five in wheat; one in potatoes; 35 in meadow; the remainder is occupied with the orchard, garden, etc. Corn averages 50 bushels per acre. The hay crop this year will amount to 80 tons. We don't use commercial fertilizers. Other farms near by of less size and better land beat mine in the amount of stock kept. But hay at present isn't worth hauling to the railroad, where it brings only about $4 per ton. Hogs pay best at three to five cents per pound live weight. The only way in which we can make any money on steers is by buying them when two or three years old and keeping them over one winter only, feeding corn the latter part of the season so that they will get a good start with which to go on grass pasture. One should feed all the good hay they want, and not over-stock his pastures. The animals should be sold right off the grass in August or September at from $3.50 to $5.00 per cwt. One neighbor paid $32 per head for three-year-old steers in February, and in September sold them fat, off good pasture, delivered at the railroad, for $4.80 per cwt. bringing $65 per head, and he did not feed over $25 worth of corn. Another began feeding corn heavily in the early fall and by the following June he had fed to four steers 500 bushels of corn at 20 cents per bushel and then had to sell them, weighing 1,580 each, at $3.50 per cwt. Result loss, of course. Pigs picked up corn after steers. What prices do the Cranbury farmers get?

BETTER COWS.

W. E. R., DOVER, N. H.—A week or two ago I read in the RURAL an article headed: "Better Cows and How to Get Them." This would not be a hard problem to solve if farmers would give up some of their old notions and use some of the chances they have to improve their stock. When I came here, nearly four years ago, I wanted to buy a Jersey cow, and found them very scarce. Some of my neighbors told me I had better not get a Jersey, as Jerseys were wild and tender and not worth anything for beef. I bought what was called one of the best cows around here. After keeping her awhile, I concluded that my neighbors' standard for a good cow was rather low or that mine was high. After looking around a good deal, I bought two Jersey cows and sold the first one for beef. I got a Guernsey heifer from a friend in Massachusetts, and thought I would raise my own cows; but when I wanted to find a bull to use there were only scrubs; so I got a Guernsey bull from some of the best stock in Massachusetts. There are no other Guernseys about here that I know of. I am much pleased with mine, and prefer them to Jerseys. I charge only one dollar for the use of the bull; but some think that too much and will drive their cows to a scrub bull whose services they can get for 50 to 75 cents. But many who keep good butter cows bring them to my bull. I think that a man who is not willing to pay a dollar for the use of a good Guernsey bull does not deserve a good cow, but ought to have a scrub. A farmer who is making butter would be better off by keeping a Guernsey or Jersey cow until she was five years old and then knocking her on the head and burying her, than by keeping such a beast as many of the farmers hereabouts keep until she also is five years old, when they get a good price for her beef. Some of the farmers say: "My cows are the same as my father kept, and if they were good enough for him they are good enough for me." As long as farmers think that there is more money in keeping cows that make from 100 to 150 pounds of butter per year, and that butter cows are wild, tender and expensive to keep, they will not try to improve their stock. It is hard to get them out of the ruts in which they have traveled so long. When you tell them a cow will make a pound of butter from 7¼ quarts of milk, they don't call you a liar, but they look as if they wanted to, and when you tell them that a two-year-old heifer is making about 9½ pounds of butter a week, they say: "That's doing pretty well!" There are none so blind as those who will not see.

HIRED HELP.

C. C., WATKINS, N. Y.—I believe that the question of hired help is an unsolved problem with many. It seems to me that any suggestion that will tend to the betterment of the employer without injuring the condition of the employed, is a step in the right direction. Nearly all that have had experience claim that the man hired by the month, who is boarded and has his washing done in the house is a nuisance, and if the man is not, the practice certainly is. Oftentimes the farmer with this monthly help finds his man has left him at the commencement of haying or harvesting for some more paying position. Many such cases have happened here this season. Besides this, the hiring of monthly help with board in the house generally obliges the housewife to have extra help. Now, the suggestion I have to offer is that the farmer should have a tenant house and let the man board himself as far as practicable. Many small places can be purchased here on which there is a small house and barn, for about what the land alone is worth. Give such a building a coat of paint and a few repairs and the tenant house is ready. One small lot that I know of paid for itself in four years, so that the outlay was not very heavy. This way of hiring relieves the housewife of much unnecessary labor, and a man hired in this way seldom leaves his employer without good cause. Many times the tenant's wife can be hired to help in the house when such help is most needed. Of course, this only provides for one hired man, but this is all that nine out of 10 of the farmers here hire for the season, besides day help. Now let us compare the rough cost of the two ways. The tenant generally gets here about $200 per year, house-rent with a garden, cow-pasture, and fire-wood. This same man could not be hired for less than $20 per month for eight months. Without counting the extra work required in the house from the monthly hand, where is the saving? About all that need be said about the treatment of the hired man is: "Be a gentleman yourself and treat him like one." If you are his superior, show it by the use of pure language, good, temperate habits and a Christian-like behavior. With regard to work, 10 hours in the field are enough for the hired man, and I believe the farmer will get fully as much profit from 10 hours' work as from more. This way of hiring and treating a man will make an honest, industrious citizen of him if anything will.

"SEEDING IN THE CORN FIELD."

O. C. HOWE, BERRIEN COUNTY, MICHIGAN.—The R.-N.-Y. is very properly discussing all topics that pertain to the better methods of farming. I was quite interested in the issue of June 29 which treated of the subject of "Seeding in the Corn-field," and eagerly read the different ideas advanced. Clover is quite frequently sown in the corn-field by farmers here. It is sown after plowing the land the last time. No one sows except for pasture and to restore the fertility of the soil. We recognize the fact that wherever clover is growing upon land the latter is getting richer and consequently we sow it whenever we can. Prof. Latta has the right idea when he says that "with favorable weather in July and August the seeding would doubtless do well," and that "much would depend on these two months." With us the seed is sown in July or very late in June. If there be rain enough in July and August to carry the seed into the ground and keep it alive and growing, one will be quite likely to get a good stand of clover. Contrary to the advice given by Prof. Wing, I should sow as soon after the ground is plowed as possible. The seed then falls into the little crevices and is soon covered with earth. If not sown at this time, a few dews will form a crust over the soil so that the seed will have to be dragged in. Last year the weather was too dry and I lost my seeding. Two years ago I was only partially successful, but had enough for pasture. This year the weather is specially favorable and some of the clover is up now. If the frequent rains continue I shall expect a good stand. I think the practice a good one, when it works at all, for it furnishes pasture during the summer months and makes the field richer for wheat. I have adopted this method because it allows one to farm more extensively without seriously robbing the soil.

GRANULATION OF BUTTER.

P. C., MILFORD, N. H.—J. M. C., of Hopkinton N. H., says that I ought to know that granulation is perfected by stopping the churning process at just the right time. That is all right; but if one stops the Blanchard Churn at that time, are not the floats and inside of the cover covered with cream that is not churned, unless it has previously been scraped off. That has been my experience with a churn with inside floats, similar to the Blanchard. Now about the cleaning: we always wash the churn thoroughly and the Stoddard can be fastened upside down and the cover be left on the bottom of the churn, and it is not shut up tightly and so has not a close and unpleasant odor which other churns sometimes have. Now about the end-over-end motion of Stoddard requiring more watchfulness than the gentle motion of the floats in Blanchard, I can always tell by the glass in the cover, without stopping to look, just when to stop churning with the Stoddard, and the granulation is perfect, and I have heard one man who saw me churn and who has a Blanchard Churn, say, as he saw the perfect granulation: "I guess the next time I want a churn I will get a Stoddard." J. M. C., likes the Blanchard because he has used it so long and it is a good churn I admit; but for great ease in cleaning and perfect granulation of butter and ease of running, I prefer the Stoddard and think that nine out of 10 persons who are not especially interested in either, after seeing both in operation, will choose the Stoddard.

SOME SILO CROPS.

O. T. B., SOUTH EUCLID, OHIO.—I have never put oats in a silo, but I have fed oats and peas sown together to milch cows with good results. In 1888 I filled two pits with clover put in whole so that they were about four feet deep when they had settled; they were covered with loose straw and rails. The silage did not keep well; it dried out about half way down, not being compact enough to exclude the air. It came out musty, or covered with white mold, as seen in mows where clover has been put in too green. The bottom part was very fair. If I had put it all in one pit there would have been only one top and only half as much damage would have been done. Cows ate the whole with good relish. I would not recommend clover as an ensilage crop; I would prefer to cure it as hay and feed it in connection with corn silage. I put six loads of millet that had been killed by frost on top of corn silage, covered it in the same way as the clover, and opened it in three weeks. It made fair silage; but it was not equal to that from corn. I had trouble from the milk souring while I was feeding it. Corn is the stuff for ensilage.

BUTTER COLOR FROM ANNATTO AND GRASS.

W. P. W., MONROE, WIS.—In the RURAL of July 27, under the head of "Brevities," appears the following astonishing assertion. "The dairy-worker who colors butter in the churn works on the principle employed by the one who depends upon green grass for a color. They both aim to get vegetable (?) coloring matter into the product. In one case the cow does the work, and in the other the dairy worker does it." That is "bosh" and wholly unworthy of a place in the RURAL. The dairy-worker who uses dyestuff to color butter for sale, perpetrates a fraud, and intends to cheat when he does it. There is no demand anywhere from consumers for annatto-colored butter or cheese. The demand for these is wholly confined to the producers and sellers.

INSECTICIDES; A MIXER.

C. D. W., GRAND BAY, ALABAMA.—I was not much surprised at reading the editorial in the RURAL of July 13 on insecticides; but I would have been surprised had I read it in any other journal with which I am acquainted. It shows so clearly that the interests of its patrons are not subordinated to its advertising columns. Now for a good mixer; take for a pattern a barrel churn, only run the axis through the heads, with a crank on one end, and a piece of a stave cut out for a hand hole; fill half full; put in a few stones as big as your fist, if you like, and the thing is ready.

STEPHEN HOYT'S SONS, NEW CANAAN, CONN.—We hardly think the RURAL'S test of the Yale Strawberry is sufficient to judge of its success in the Rural Grounds yet. It has been one of the worst seasons for strawberries on record. Ours did not do half as well this year as they did last.

What Others Say.

SOILING AND EXERCISE: The Jersey and Guernsey cows, Henry Stewart remarks, are types of the most profitable of all dairy animals. These animals for many years past have been fed on the soiling system. Pasturage is clearly impossible upon an island of only 45 square miles or less than a square of seven miles each way, with only 4,000 acres of pasture and 75,000 or 76,000 cows, so that the cows are kept in confinement almost wholly, and in pasture are tethered within as narrow bounds as will afford the single meal only at one time. But under this system the Jersey breed of cattle has been brought to the highest point of product and profit, and has been always free from the common diseases of cows. No one hears of tuberculosis or pleuro-pneumonia in that pleasant and densely-populated island. To take American instances, we shall find that the highest and the most healthy cows are found where soiling is practiced, and whenever a test has been made of soiling, that is, feeding in yards or lots and stables on green fodder, cut and brought to the cows, as against pasture, the soiling, with its restfulness, quiet, and economy of food, has always given at least 25 per cent. more product with less consumption of fodder

SAMPLES AND COMMENTS.

THE WESTERN RURAL says that every farmer who provides himself with a beautiful home, surrounded by green lawns and winding paths, a well cultivated farm, and all that makes life pleasant, is a blessing to any neighborhood. Were there no shiftless farmers, or tramps, or paupers; if all classes could in some way be induced by proper training to become self-reliant citizens, the millenium would be on its way hither.....

ONE'S WHOLE DUTY to oneself, is one's first duty to his neighbor.....

THE MASSACHUSETTS PLOUGHMAN remarks that the Champion Quince is said to be preferable to either the Orange or Rea's Mammoth. It may be in the South, but those who act upon the above well-meant advice will, in the R. N.-Y.'s estimation, have occasion to regret it. The Champion is too late for the North.....

PROF. S. W. JOHNSON makes the valuable note, in a bulletin just received, that the fertilizing value of fine bone is much greater than that of coarse bone. The latter may lie in the ground for years while very fine bone is readily decomposed and taken up by plants. The improved condition and increased value of our bone-manures are to some extent results of the action of the Connecticut Station which in the year 1879 first carried into effect the method of valuation based on the mechanical as well as the chemical analysis. Nitrogen in the finest bone is now worth 16½ cents per pound, while that in the coarsest bone is valued only at 8½ cents, and phosphoric acid is valued at seven and four cents in the two grades respectively. Very finely ground bone is, at present, one of the cheapest sources of quickly available nitrogen and phosphoric acid.....

AGAIN he says that the price of castor pomace has advanced $5.00 a ton since last year, and in consequence it has become one of the most expensive sources of nitrogen, while last year it was one of the cheapest. Cotton-seed meal has also advanced in price but still remains the cheapest source of available nitrogen.....

AS AN illustration of the long time chess seed will lie in the ground dormant, a member of the Elmira Farmers' Club mentions in the Husbandman, the removal of an old barn which had stood on the ground 40 years. The same season a luxuriant growth of chess sprang up and covered the unoccupied land. Had this particular piece of land been sown to wheat, many farmers would have considered it a convincing proof of wheat turning to chess.....

SOMETHING NEW IN ROSES: We find the following in our lively contemporary Popular Gardening:

"The Editor of the RURAL NEW-YORKER has had remarkable luck in hybridizing roses, according to his report. A cross ascribed to Harrison's Yellow upon Rosa rugosa has brought out a new rose with flowers so much like those of the famous General Jacqueminot as to deceive good judges. The foliage, however, is different, being more like that of the Rugosa parent, and, best of all, it is less subject to the attacks of insects than anything in its line we now have, for this one is a perpetual bloomer. Notwithstanding Mr. Carman's reputation as a careful hybridizer, the question will naturally arise in the minds of many as this new-comer is compared with its assumed parents, which so widely differ from it, whether there may not be some mistake as to the parentage. However that may be, such a rose as Mr. Carman describes is a welcome addition to our all too meager list of hardy, vigorous, handsome, perpetual kinds."

It is not wise to be positive as to many things, but there is no room to be anything else in the case of our rose crosses. We have never raised a rose from any seed except from Rosa rugosa. That, it will be admitted, settles any question as to the maternity of the seedlings. The rose in question was produced by using pollen from Harrison's Yellow upon R. rugosa. No other pollen up to that time or during that season had been or was used. As self-Rosa rugosa seedlings come nearly true from seed it will not be questioned that the plant in question *is a hybrid*. If so, Harrison's Yellow is the male parent, since every bud of Rugosa operated upon was carefully emasculated before the anthers were ripe, and carefully covered with fine tissue-paper until the pollen was applied. The tissue-paper in all cases was then at once replaced and not again removed until it was seen that fruit formed or failed to form.

The next year pollen was used from Hybrid Remontants upon R. rugosa that happened to furnish it when needed. The male parentage of this second year's batch (or what is left of them) is therefore unknown. Four or five have bloomed, showing them to be rather more interesting as curiosities than valuable for any other purpose. The third season's batch originated in the same way as the second. There are about 40 of them. They have not as yet bloomed. The foliage of these as of all others, varies indefinitely—not one having that of R. rugosa and yet as they grow older, all showing some trifling resemblance—generally in the texture and venation of the leaf.

The present year we have used chiefly the pollen of Teas and Hybrid Teas upon R. rugosa. The result thus far is that we have not less than 250 plump heps each one of which will give an average of 50 seeds. It will be seen that the R. N.-Y. is making a pretty thorough trial of R. rugosa hybrids which involves an amount of painstaking labor that we should be foolish to undertake without the absolute knowledge that they are really hybrids without the shadow of a doubt. Our good friend the Editor of Popular Gardening is cordially invited to come and inspect the results of our work for himself.....

THE Orange County Farmer is glad to note an increasing interest in that part of the world in the matter of breeding draft horses. The farmers of Orange County and vicinity have tried the trotting horse business and have never made it profitable, but there is no hazard in the draft horse. He is ready for market at three and four years old, always commands a fair price, little blemishes do not affect his sale and he is as easily raised as a steer. There are many things to be said in favor of this branch of farm work.....

THE Western Rural is of the opinion that for a real bright, Pilgrim-pure, clear-cut, financial idea one should go to a New England man. It says that one has just advised a young man who has two thousand dollars, and wishes to buy a farm to loan the two thousand to some farmer and go to work for him by the month. The writer thinks the young man will own the farm in due time.....

For Sleeplessness

Use Horsford's Acid Phosphate.

DR. C. R. DAKE, Belleville, Ill., says: "I have found it, and it *alone*, to be capable of producing a sweet and natural sleep in cases of insomnia from overwork of the brain, which so often occurs in active professional and business men."—*Adv.*

DIRECT.

——N. Y. HERALD: "A curious discovery shows that cider is a dangerous beverage, for it propagates typhoid fever."

——TROY PRESS: "The man who ought to listen and learn usually does most of the talking."

——O. C. Farmer: "This talk about fancy prices is, to say the least, misleading. Because one man happens to get a private customer who is willing to pay a fancy price in order to secure a regular and uniform quality of butter, is no proof that his butter is any better than that of some of his neighbors who must be content with the market price. Some men are fortunate enough to get special customers and prices. But there are not enough such customers to go around. The bulk of the product must be sold at market prices."

——PROF. I. P. ROBERTS: "Why put manure on your fields in the spring? Is that the way the Lord manures His farm? Is that the way He has reared these great oaks and chestnuts and pines? No; He raises a plant to feed an animal to make fertility, and He always spreads manure in the fall."

——PROF. HENRY, in the Western Farmer: "I should say that a common two-strand, galvanized barb-wire, well put up, is superior to many of the rods as put up by "agents" at great cost. If one intends to use barb-wire it would be better to twist half a dozen strands into one than to use a single wire. Having done this, bury the lower end of the wire in moist earth, digging if possible down to water; or, all the better, running the wire into a well or cistern below the water. Without a good ground connection the wire may be more than useless. Having the wire properly "planted," attach it firmly to the building every two or three feet by common staples, just as you would to the posts when using the wire for fencing. The common practice of using glass thimbles for insulators to keep the rods away from the building is altogether wrong; agents no doubt use this plan to add to the expense and mystify people. Carry the wire to the highest points of the building, and let it rise several feet vertically, supported by a staff nailed to the roof. The wire may be supposed to insure safety for a distance in every direction equal to its hight above the building. Thus, if it rise eight feet above the peak of the house it guards a circle sixteen feet in diameter."

——"OF all humbugs, the lightning rod man is usually the greatest, and if we had all the money he has taken out of the pockets of Wisconsin farmers, without proper equivalent, we could put a fine library into every Grange hall in the State, and have enough left to pay the expenses of a few hundred young men up at Madison this winter to attend the short agricultural course."

——FARMERS' REVIEW: "The arguments to be used in favor of administering chloroform to animals are precisely the same as those for its use for the human subject—first, that all pain is avoided; and secondly, that the stillness produced in the animal tends to increase the ease and safety of the operation to be performed."

——JOSH BILLINGS: "We are so avarishus that even when we trade with ourselves, we go for getting the best end of the bargain."

——HOARD'S DAIRYMAN: "If there ever was a man whose stingy avarice beats the very breath out of himself, it is the man who will undertake to make a cow really profitable without feeding her liberally, of good milk-producing food. The punishment goes a step farther. Even after he gets converted to the gospel of liberality, he is beaten, unless he is just enough to himself to get a *good* cow into which he pours this liberal supply of feed."

——"THE prayer of every dairyman should be, 'O Lord deliver me from the folly and certain punishment of being stingy to my *own* cows.'"

——VERMONT WATCHMAN: "The future of farming will be revealed when the cities fail to be able to absorb nearly all the rising talent and energy of our people. When that time arrives (and it is near), we shall see fine agriculture begin to take gigantic strides. The field is boundless; the opportunities are rich. All that is waited for is *men*! It makes the soul sick to see how the opportunities and possibilities of farming in New England are overlooked."

——N. Y. TIMES: "A farm is always worth more than it will sell for. The farmer cannot live on the proceeds of the sale without spending his principal, and risking the chance of poverty or dependence, should he live longer than his probable term."

Hood's Sarsaparilla 100 Doses One Dollar

Summer Weakness is quickly overcome by the toning, reviving, and blood-purifying qualities of Hood's Sarsaparilla. This popular medicine drives off that tired feeling and cures sick headache, dyspepsia, scrofula, and all humors. Be sure to get Hood's Sarsaparilla.

JOHNSON'S ANODYNE LINIMENT ESTABLISHED 1810.

For Internal and External Use.

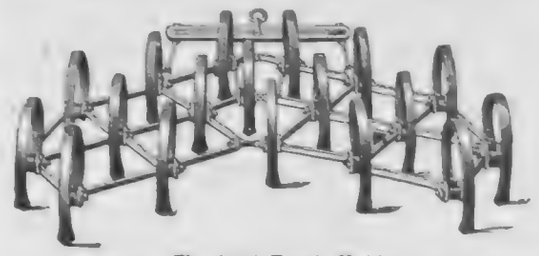
Stops Pain, Cramps, Inflammation in body or limb, like magic. Cures Croup, Asthma, Colds, Catarrh, Cholera Morbus, Diarrhœa, Rheumatism, Neuralgia, Lame-back, Stiff Joints and Strains. Full particulars free. Price 35 cts. post-paid. I. S. JOHNSON & CO., Boston, Mass.

HENCH & DROMGOLD'S

All Steel Frame Spring-tooth Harrow

A WONDERFUL IMPROVEMENT.

TEETH QUICKLY ADJUSTED BY ONLY LOOSENING ONE NUT.



The best Tooth Holder ever invented.

The tooth is held in position by a Ratchet with which it can be adjusted so as to wear from 15 to 18 inches off the point of the tooth, which is four or five times as much wear or service as can be obtained from any other Spring-tooth Harrow in existence.

Agents wanted. Catalogues free.

HENCH & DROMGOLD, York, Pa.

FEARLESS.

This Threshing-machine received the two last **Gold Medals** given by the New York State Agricultural Society; and has been selected, over all others, and illustrated and described in that great work, "Appleton's Cyclopedia of Applied Mechanics;" thus, establishing it as the **standard** machine of America. **Straw-preserving Rye-Threshers, Clover-hullers, Ensilage-cutters, Feed-mills, Fanning-mills, and Wood Saw-machines;** all of **the best** in market. The **Fearless Horse-powers** are the most **economical** and **best** Powers built for the running of Ensilage cutters, Cotton-gins, and general farm and plantation use. SATURDAY, AUGUST 24, 1889

PRES. LYON page 563 pronounces the Erie and Lawton Blackberries *not* alike. To the R. N.-Y. the Erie seems a hardier variety.

Read "Farm Libraries" page 568. *What do you think of "At A Fair"* page 556?

MARCH, if you would keep up with the procession. *March*, MARCH—there is no escape from it! It is the weapon of the industrious against the idle; a weapon that God has placed in their hands as a means of equitable and humane self-preservation.

"The Red Polled I consider next to the Devon as general purpose cows."—L. F. ALLEN, page 556.

PROF. COOK, of the New Jersey Experiment Station, reports, in a late bulletin, what the R. N.-Y. has so persistently endeavored to impress upon its readers.

As a rule, he says, the fertilizer which contains the greatest amounts of nitrogen, phosphoric acid and potash is the cheapest; for the cost of manufacture, freightage and rate of commission are the same for high-grade as for low-grade fertilizers, and *the labor on the part of the farmer is increased as the grade of the goods decreases.*

The R. N.-Y. confidently anticipates the time when there will be no demand whatever for low-grade fertilizers.

"When enumerating cut-worm remedies we should not forget to mention clean culture."—C. P. GILLETTE, page 557.

THERE will be no Pennsylvania State Agricultural Fair this year. The State Agricultural Society, owing to great carelessness and mismanagement, has financially collapsed. Last Wednesday the State fair grounds at Philadelphia together with the buildings, franchise, etc., was bought in for $2,500, by the Reading Railroad Company, which forcelosed a mortgage for $25,000, which it held on the property. Investigation shows that the Association also owes an aggregate of $80,000 to various other parties. It is to be hoped other fair associations which may be disposed to run recklessly into debt, will take warning from the plight of this "terrible example."

"But look at it, you who wish well to the babes in a million cradles! What about this modern narrowing down of human activities and observation?—OLIVER HOWARD, page 558.

THE R. N.-Y. wants to know whether hay can be satisfactorily baled from the field. A number of our readers who have tried this experiment report failure. The hay will not keep in good condition. Here is a note from a manufacturer of hay-presses, which ought to have weight:

"We experimented with our machines in baling grass as cut from the field, but we did not find that it kept. Others claim that they have baled grass that was partly cured, and that it kept well; but we are of the opinion that it would not answer for general use. We know that our machines will bale it as well as any other kind; but we think no kind will bale it loosely enough so as to allow the air to circulate freely through and thus dry it out without molding."

"Where was the owner of that boy? Well, I don't know; but I do know that I would not have had that boy go through my potato field in that way, at that time, for $20 *an acre."*—T. B. TERRY, page 555.

"WHEN shall I stop the churn so as to get the best 'grain' to my butter?" There is probably no one dairy question that is asked more frequently than this. The usual answer is: "When the butter has formed in lumps about the size of wheat kernels." The man who gives this answer doubtless thinks it conclusive. The learner often sighs for something more definite. "About the size of wheat kernels" will not tell it all. The R. N.-Y. will give its readers something more definite. One of the best butter-makers in New York State will have photographs taken of his butter just as he stops the churn. We will print these photographs together with one showing the effects of too much churning. These pictures will tell more than a volume of words ever could.

"This plan of planting corn will give more stalks and sunshine to the acre than any other, and experiments have shown that 17 *inches in the drill is about as close as our large corn will grow and produce ears."*—J. C. STRIBLING, page 556.

THE R. N.-Y. WOMEN'S POTATO CONTEST.

THE reports of those engaged in this contest must be received at this office on or before October 1st.

"What shall I decorate?" asked an insipid city boarder of me. And I showed her the butter-crocks, churn, hen-coop and mowing machine. "Take your choice," I said. She looked at me softly, and then sighed sadly."—JERSEYISMS, page 557.

$25.

TWENTY-FIVE dollars are offered by the R. N.-Y. as follows: Fifteen dollars for the largest and best shaped R. N.-Y. No. 2; $10 for the second-best. Description and weight should be sent in before November next. Those only who may be entitled to one or the other of the above prizes, *as judged by their own reports*, will be asked to forward the specimens to this office.

"A farmer who is making butter would be better off by keeping a Guernsey or Jersey cow until she was five years old and then knocking her on the head and burying her, than by keeping such a beast as many of the farmers hereabouts keep until she also is five years old, when they get a good price for her beef."—W. E. R., page 560.

THE R. N.-Y.'S POTATO CONTEST PLOT.

AS has already been stated, the Women's Contest plot of the R. N.-Y. was selected on a low piece of land in anticipation of a very dry season. The vines made a rank growth until the latter part of July when the leaves began to blacken and in a few days all were dead. Several hills were examined and the tubers were found to be a mass of inexpressibly putrid rot. The varieties were R. N.-Y. Nos. 2, 3, 4, and Brownell's Winner. Whether on high or low land potatoes in the vicinity of the Rural Experiment Grounds are rotting as they never have been known to rot before.

It is believed that it is not alone the excessively wet season that has caused the rot, but that the serious injury which the vines sustained from the flea-beetle in the early part so weakened the plants that growth being checked, they had the less chance to recover in a soil constantly wet to saturation.

The yield of the *regular* contest plot will probably go beyond that of last year, but on that, too, the vines are nearly dead and from an examination of several hills, it is feared that rot will destroy so considerable a portion that it will be needless to call upon the judges to perform a task which they so kindly imposed upon themselves at the R. N.-Y.'s request.

"For general reading there are some books necessary to every household: first of all of which is the Bible; not the big, brass-clasped ten dollar book always untouched on the parlor table and fit for the only use to which it is put, the stowing away of relics of all sorts, from the children's valentines to the sacred locks of hair; but the convenient-sized reference Bible for the family reading and Sunday School work."—M. J. CARPENTER, page 568.

THE POTATO CROP.

WHAT are the facts regarding the condition of potatoes? It seems evident that the Eastern crop is considerably damaged by the continued wet weather. It may be that this damage is less than is anticipated. Possibly the accounts of rotting refer to small localities and that the real damage will have comparatively little influence on the total crop of the country. The reports from the East are quite general, however, and indicate at least that the appearance of the crop is not promising. The actual state of affairs cannot be determined until the potatoes are dug. When a man finds rot in his field during such weather as we are now having, the trouble naturally looks large to him and he will frequently find an agreeable surprise when he digs the crop. The Western crop seems to be irregular—some fields are very good and others very poor. We should say that, on the whole, the crop at the West will be fully an average one. The deficiency will be at the East and the size of the deficiency will determine the price. As matters now stand, prices should be firm and a little above those of last year. There are one or two other points about the crop that are interesting just now. Does coarse stable manure stimulate rot in a damp season? This is suggested by Dr. Halsted. We hope our potato growers will tell us what they think about it. It seems sensible to argue that potatoes should not be planted next year in fields where the rot prevails now. Many farmers plant potatoes on the same ground, year after year. This season of rot will probably make it necessary for them to begin a system of rotation. It would appear that there is little danger to public health in the rotting tubers. Prof. Stockbridge, of Japan, recently declared that decay in vegetable material induced the formation of a poisonous principle, but as this principle is always destroyed in cooking and as potatoes are never eaten raw, the danger from this source is not worth mentioning.

FORWARD—MARCH!

IT has been the unswerving policy of the RURAL NEW YORKER ever since its present management founded it upon the ruins of *Moore's* R. N.-Y., while retaining its distinctively characteristic features, to inaugurate every year, in one way or another, progressive changes which should at length entitle it to be ranked in *appearance*, as well as in contents and originality, with the most popular and refined magazines and general-news periodicals of the times.

A valid reason has never occurred to us why the farm and garden interests of our country should not be represented by journals in all respects the equals of those which represent other industrial interests of minor—certainly not of paramount—importance. Accordingly, we have now to announce that, agreeably with our progressive plans, the R. N.-Y. will hereafter be printed upon supercalendered paper of a weight which shall secure its readers the full benefit of another feature of which farm journals printed upon inferior paper cannot avail themselves, *i. e.* the employment of new photographic etchings. These are absolutely faithful reproductions of the photographs themselves, and, as is confidently believed, are so far superior, for most kinds of portraiture as to fully warrant the extra expense incurred in their use, and the consequent substitution of paper of a weight and finish essential to their perfect reproduction.

The proprietors of many of our respected contemporaries have seen fit to reduce the price of their publications from time to time, during the past five or six years, the evident object being to secure a wider distribution—a commendable object, surely, in so far as it could be secured without any notable depreciation in their value. This reduction in price, however, has later become general, so that it is problematical, at this time, whether the earlier increase, so induced, has been sustained, and whether, if not sustained, they can be conducted without a corresponding economy in the cost of their publication.

The paper upon which this edition of the R. N.-Y. is printed is the same as that which it is proposed to use in the future, or at least until it may be deemed judicious to substitute a still better grade. The first issue in September will show still further notable changes which will speak for themselves, and, as we confidently hope, merit the approval of our readers and secure a more extended constituency for the coming year.

All readers are respectfully referred to the R. N.-Y. advertisement on the third cover-page. That states, in a few words, what we have to say to both agents and subscribers.

A small cow, with the right kind of machinery in her, can get all the milk solids out of a given amount of feed as well as a big cow. But if you have good, big cows, and they give you a fair profit, keep them, but breed them to the smallest good dairy bull you can find, and if the result is a more concentrated cow, I think you are the gainer.—A. L. CROSBY, page 558.

BREVITIES.

READ the last paragraph of Dr. Hoskins's article on page 557.

THE R. N.-Y. Dorking hens are now laying well while hens of other breeds are decidedly lazy.

All readers of this paper are requested to read the advertisement on the third page of the cover.

THE first report of the Women's Potato Contest comes to us from Mrs. L. E. Wood, of Dade County, Mo., and an excellent report it is.

WE will tell all about the new "Butter Extractor" next week. We have, also, a fine report of two of the N. Y. State Dairy Conferences.

THE next symposium will discuss the economy of the practice of pasturing meadows. Mr. C. S. Rice will present the matter in a way that will doubtless startle many of our readers.

THE R. N.-Y. has in preparation an illustrated article on the newer blackberries, which may serve to guide those who are in search of such information. The illustrations will be photo-engravings from nature.

JUST now the demand is for young, round beets to be cooked whole. They must be dark-colored. No matter how good light-colored beets may be, they will not sell well. Here is a hint for consumers who don't care for "fashion."

THE second crop of potato beetles were all on hand for a great celebration. Just as they got a good taste the vines began to die. The beetles were left without food. This fact and the continued wet weather led the R. N.-Y. to hope that we may have fewer beetles next year.

WHILE there is a division of opinion as to the outcome of the corn crop, there is a general belief that the oat crop is the largest ever harvested in this country. The rains have injured the grain somewhat, but there is plenty left. Will oats be much lower in consequence of this large crop?

MR. J. N. MUNCEY not long ago, gave, in these columns, some figures showing the cost of supplying his family with sugar, coffee, flour, tea and other necessaries. It would be very interesting if we could compare these figures with those of other households. We have received one or two statements already and we would like to hear from all who keep accurate accounts. For instance, is the sugar bill of a N. Y. farm family greater per member than that of the Iowa family described in Mr. Muncey's article?

Field Crops.

(*Continued from Page* 558.)

It would be interesting to gather statistics this season to prove the truth or error of this opinion.

An extended inspection of potato fields together with many reports received from all directions shows that this is to be a potato rot year. In many places where large crops of the finest potatoes were naturally expected the yield will not be half and that of inferior quality. This is principally due to the attack of the mildew, which, starting in the middle of July upon the upper leaves, has spread to the stems and probably in many instances to the tubers. Now the vines are all dead, and of course all growth or maturing of the potatoes has ceased. The mill cannot grind with the water that has passed, neither is there any remedy that will restore life and vigor to dead potato vines. It is too late to apply a remedy. That must come next June upon a succeeding crop if at all.

The chief point now is to do the best that can be done for the potatoes that are on hand. If it is borne in mind that moisture and warmth are the prime conditions for the growth of the rot in the vines; and that the same conditions will favor the rotting of the potatoes, it follows naturally that, other things remaining the same, it is wise to place the tubers in a dry cool place. The heavy rains of the last week have soaked the soil and carried down many of the germs (spores) of the rot from the leaves to the potatoes. As soon as possible therefore the tubers should be taken from the soil and the exposure to the germs. After digging leave them to dry thoroughly in the field and then store them in small masses where they will be kept free from surface moisture and in a cool dry airy place. Shallow bins may perhaps be best. Watch the bins from week to week and remove any affected potatoes before they become the centers for rapid decay. The potatoes will be worth looking after this fall and winter.

New Jersey Experiment Station.

SELECTION OF SEED.

W. B. PRATT.

OUGHT small kernels of grain to be riddled out and only the larger ones be used for seed? Should the unit be the single kernel or the whole head? These are important questions and are answered theoretically and practically in one and the same way by nearly everybody. Are they rightly answered?

Doctor Sturtevant announced from the Geneva Experiment Station a few years ago, what some practical farmers have already learned, that neither tip nor butt kernels of the ear should be rejected. If the whole ear should be the unit in the production of Indian corn, should not the whole head or panicle of other grain also? It is often said of some particular variety of grain once popular and profitable, that it appeared to run out and its cultivation was therefore discontinued. The remedy in all such cases has been sought in a change of seed from one section of country to another, or in trying some new and perhaps loudly heralded variety. May not the cause of the deterioration have been in the farmer's practice of planting but a part of the head instead of the whole of it? May not the outer, small tip kernels be essential to preserve the length, balance and completeness of the heads of the future crop and may not a failure to give them an opportunity of doing so tend to cause a general decline? Small kernels are a feature of the normal panicle; every seed planted may be of full size, yet there will be "screenings" in the crop; and these facts make questionable the practice of rejecting the small berries as seed.

Twenty-five years ago I bought some thin soft shuck seed oats bearing the name "Golden Yellow," and I have used them continually since. They have grown white in color and have run down both in yield and weight. For several years they averaged some 70 bushels to the acre, in favorable seasons weighing as high as 39 pounds to the struck bushel. Then the yield began to run down to 65 and 60 bushels, and so on to below 45, the berry steadily growing lighter in weight. I reasoned that this could not be owing wholly to bad seasons, nor at all to a soil of lessened fertility, and that possibly my practice of grading seed and sowing only the largest kernels may have had something to do with it. Thereupon I changed my practice and have since run the seed over a fine screen instead of a coarse one, dropping out but few of the small kernels and merely blowing out the straws to facilitate distribution from the seeder. Within two years after this change of practice, improvement in the yield began to be apparent, getting last year up to 60 bushels, with prospects of further increase the present season.

My conclusion is that the correct way of preparing seed to prevent "running out" would be to weed out the foul stuff from so much of a crop as will be needed for the next year's seeding; or, better still, to sow the grain for whatever seed may be needed in wide drill marks and by cultivation insure absolute cleanliness, and then sow every kernel, large and small, that grew on the seed plot. How the small tip berries operate to maintain the future panicles in their original perfection and thus prevent decline can not perhaps be explained; but that they do have such effect is reasonably certain.

I have heard it claimed that neither large nor medium-sized nor small potatoes should be exclusively planted, but that seed should be promiscuously taken from tubers of all sizes. My own general practice has been to plant a medium-sized, single potato in a hill, and I am quite sure that there has been steady deterioration following this selection. It may be worth while for experiment stations and young farmers to test this matter, both as to potatoes and the cereals, and ascertain if what would seem to be an unnatural tendency to "run out" in grains and vegetables that are as old as history, may not be traced to a disturbance of Nature's balances.

Prattsburgh, N. Y.

Horticultural.

A LITTLE EXPERIENCE IN THE FRUIT GARDEN.

A YEAR ago last spring the writer set out a small fruit garden. It contains 100 rods of ground. The rows of grapes, raspberries, blackberries, etc., were put eight feet apart. So far all right. But a friend advised me (I was entirely green at the business) to put a row of stawberries between the raspberries, etc., all through the garden. I wanted to set out a new bed of strawberries of about that size, and thought this a good plan. Now, I do not think so. I wouldn't do it again. What did I save? Why the use of a few rods of land. What is that to a farmer with plenty of acres? What was the trouble? Why I could do but little of the cultivation this spring with a horse. Much had to be done by hand, at greatly increased expense. When I found the grape roots, and those of the raspberries and blackberries too, occupying almost all the ground, I began to see that they were stealing from the strawberries and the strawberries from them. This wasn't what I wanted. I desired to give all the best possible chance. And then, again, the tramping of the ground while picking the strawberries (it rained most of the time) and also while taking up plants in the spring, left this, my pet garden, in a shape I never allow a field to get in.

But never mind. We had perhaps 30 bushels of strawberries and raspberries any way, and the former are all cut up now, and the coast is clear to attend to the other plants. But I paid an awfully big rent for the little land that was in strawberries. Another time I would put them on land by themselves, so that I could do more of the work on them and the other small fruits with a horse, cheaply, and so I could take better care of both.

T. B. TERRY.

THE LAWTON AND ERIE BLACKBERRIES.

WITHIN the past year the opinion has been frequently expressed, by persons of high standing as horticulturists, that the Erie Blackberry is merely the old Lawton or New Rochelle, re-introduced under a new name, and so confidently has this conclusion been put forth that, to some extent at least, it is apparently being acted upon by planters, if not also by nurserymen and dealers. Having both growing and fruiting on my grounds in considerable quantity, I was impelled to institute a comparison between the two. This allegation attracted my attention, in 1888, at too late a date for a comparison while they were in fruit; but an obvious similarity was noticeable in their habits of growth, save that the Erie appeared to be of lower and more spreading habit, with somewhat more numerous and stronger spines.

Both are now, (August, 1889), fruiting freely in adjacent rows, under the same mode of treatment, having been planted in the spring, of 1888. The peculiar differences already mentioned are even more noticeable than they were last year; in addition to which, the Erie showed ripe fruit on August 1; while none appeared on the Lawton till the 7th. In form also, the Erie, although quite as large as the Lawton, is shorter and more regularly rounded. Of the 20 or more varieties growing on my grounds the Erie is one of the most vigorous, and also the most unpleasant to handle, on account of its strong and hooked spines. As to its relative productiveness, and its consequent value as a market variety, I am hardly yet prepared to speak confidently.

T. T. LYON.

CHERRY TREE NETTING.

THE birds in the prairie region congregate where trees are planted on the homestead grounds to such an extent that cherry-growing without protection is clearly impracticable. This season we have covered a few trees with mosquito netting and have picked from them full crops of perfectly ripened fruit: but from trees of the same varieties not covered, we have not been able to secure a single ripe specimen. I write this to ask RURAL readers if netting suitable for this use is obtainable in this country, and if so, where? J. L. BUDD.

Ames, Iowa.

Notes from the Rural Grounds.

THE AGAWAM BLACKBERRY.

THE R. N.-Y. has never had much to say respecting the Agawam Blackberry for the reason that not until of late years has the variety been cultivated at the Rural Grounds. The plants were received from J. T. Lovett in April of 1884. They are somewhat less vigorous than the Lawton, Kittatinny or Minnewaski; the canes are less thorny and not so deeply grooved. The plants have never been seriously injured during the winter, and it is ranked in several of the Eastern States as being as hardy as the Snyder or Taylor. The berries are of medium size, that is to say, larger than those of either the Taylor or Snyder, smaller than those of Kittatinny, Wilson, Minnewaski or Lawton. The illustration, see Fig. 215, is a photo-engraving from nature and presents the size better than any descriptive words, always bearing in mind that fruit portrayed in this way always looks to be smaller than it really is.

They are firm, of a jet black color, and the drupelets, though smaller than those of larger berries, are more uniform as to size. In quality the Agawam is not excelled in our opinion. It is sweet, tender, without any core and the seeds are smaller than those of the larger varieties. It ripens with Kittatinny, though it does not remain in fruit so long. We have seen the Agawam commended as a very prolific variety, a commendation not sustained by the R. N.-Y.'s observations. Still for home use, where one is not limited to a few square feet of land for a blackberry plantation, this variety is surely worthy of trial.

Hygiene.

DANGER IN ROTTING POTATOES.

HERE is a letter recently received from a subscriber:

"Thousands of farmers alarmed at the report of potato rot, are digging the crop and shipping it to market. Many diseased tubers are being sent in this way. In view of the interest taken in the matter will you be kind enough to furnish answers to the following questions?

1. Is a potato containing the germs of the rot necessarily injurious for eating purposes?
2. What injury or disease, if any, will it cause?
3. How long do the germs live?
4. Is there any danger to public health in the general digging and marketing of potatoes known to be diseased?"

Here are answers.

FROM DR. PETER COLLIER.

I am unable to answer either of these questions concerning rotten potatoes or rather those which are diseased. At best I should think it an open question, and in practice I would not knowingly eat such potatoes, nor would I be willing to feed them in quantity to any valuable animals. That they are fed in large quantities, and apparently without any very serious results following, by no means necessarily establishes their healthfulness, but rather the ability of the animal to resist attacks of such diseases as they are capable of causing. Then, too, these bacteria, microbes, or whatever they are called, many of which are so closely associated with one or another disease, and which are claimed to produce the diseases, have such a way of being associated with each other—a sort of microscopic happy family—that it would almost seem a justifiable precaution to avoid, so far as possible, this whole crowd. What do the bacteriologists say?

Geneva, N. Y.

FROM DR. T. H. HOSKINS.

1. Not if it be well cooked. It is not known that the potato-rot fungus is poisonous at all; but it is so offensive that animals will not eat tubers even slightly affected with it.

2 There is no disease known to be so produced. The terrible outbreak of fever which accompanied the Irish famine of 30 odd years ago, was supposed to be intensified by eating partly rotten potatoes, but this never was demonstrated, and the disease was amply accounted for otherwise.

3. It is not positively known.

4. Possibly, if extensive rotting should take place in potatoes stored in cities. In such cases, the sanitary authorities would, no doubt, promptly interfere. But the very danger of rot makes the buyers very careful about collecting large stocks; and the supply will be one of hand to mouth until the true state of the case is established. I believe that the scare is unnecessary, as the great sources of supply are,—at least as yet,—not much affected. There is no rot in Northern Vermont at this date,—August 10.

Orleans County, Vermont.

FROM ROLAND THAXTER.

1. No. Unless the potato has begun to rot, when the injury would be similar to that produced by eating any other rotting vegetable matter.

2 and 3. The "germs" of the disease as it exists in the tuber consist merely of the fungus threads; that is, the vegetative part of the fungus plant. These threads of the fungus are supposed in some cases to remain inactive in the tuber until it is planted in the following year, when they develop and thus perpetuate the disease.

4. Potatoes attacked by the rot should be dug at once as soon as the foliage has become badly affected. Such potatoes are liable to rot after digging to a greater or less extent according to the greater or less virulence of the disease upon the foliage. If stored in a cool, dry place and thoroughly sprinkled with dry air-slaked lime at the rate of one bushel of lime to 25 bushels of potatoes, they will keep much better. It is unwise, however, to attempt to keep such potatoes if they can be disposed of, since a certain percentage, if not the whole of them, will rot in time.

Connecticut Experiment Station.

FROM WM. A. BUCKHART.

1. No.
2. None.
3. Not definitely known. Under favorable conditions certainly long enough to continue the infection from year to year.
4. None whatever.

It is understood that the questions relate to potatoes that are affected by the common potato rot fungus—Phytophthora infestans—and that are *apparently* sound. Potatoes which have begun to *decay* are probably unwholesome, even though they produce no specific disease.

Pennsylvania Experiment Station.

The Garden.

VEGETABLE NOTES.

WM. FALCONER.

SALSIFY.—About this time of year a large number of the outer leaves die off. To leave them on in dry weather does no harm, but in wet weather they had better be removed as they tend to increase rot. The Sandwich Island Mammoth is less subject to this than is the ordinary Long White.

SCORZONERA is not much subject to leaf rot, but a good many plants run to flower. Pull out these and discard them as their roots are tough.

PARSNIPS.—You cannot hoe among these any more; just pull up any rag-weed, pigweed or other big weeds that may come up among them; and be careful not to touch them in wet weather, else they will poison you as badly as will poison ivy. Pull out and throw away any that run to flower. The long-rooted sorts are not liable to do this, but the round or turnip-rooted sort is very apt to bolt if sown early.

RADISHES.—I sow a pinch of seed once a week out-of-doors in any open place, say, between rows of beets, carrots, celery or any thing else, but I never give it a bit of ground apart for itself. It is only a four weeks' crop from first to last. Better sow it in frames after the first of September. And about August 20th or September 1st, according to locality, sow some Scarlet Chinese for storing in winter.

TURNIPS.—Rutabagas were sown at the end of July, after snap-beans. A succession crop of Purple-top White Globe was sown August 6th after potatoes. I will sow white turnips again about August 20th, and again about September 1st. These two sowings shall be large for winter. If our falls are mild and long the August 20th sowing will be too early; but if short and cold it will be in right time and the September one a little late. But this is a risk we always have to run. White turnips that are a little too old or large are often soggy inside; hence unfit for use.

GLOBE ARTICHOKES.—Old plants have finished bearing. Cut over all old flower stems. Young plants are in full bearing. Cut off every head as soon as it is large enough for use, to insure a continuance of flower heads. Sow some seed now and winter the plumes in a cold-frame and they will be good bearing stock for next year.

SPINACH.—Sow a row of Viroflay once a fortnight till the middle of September; then put in the winter crop, I usually sow this late crop after musk-melons.

TOMATOES never were finer than they are this year or freer from rot. Dwarf Champion was about the earliest good one we had, but it doesn't bear enough. Which is the best of all tomatoes is hard to decide, but, looking over 20 varieties now in fruit side by side, I must say there is nothing among them superior to Volunteer. At the same time, if anybody brought me the fruits of half a dozen varieties of the same type, Volunteer among them, I really couldn't tell one from the other.

EARLINESS among tomatoes bothers me a good deal; and year after year's experience knocks some of my pet theories and varieties higher than a kite. This year one variety may be ahead and next year it may be away behind. But I have a tomato which is earlier than any other I ever grew and it maintains this earliness year after year. It isn't now, and never has been on the market. It is of Spanish origin, and it is an enormous cropper. But the color is pale red, the fruit uneven, and I find it has lost its foliage this year worse than any other sort. So I have come to the conclusion that my bonanza isn't worth a cent. But I will keep it for forcing.

THE DWARF LIMA BEANS.—Peter Henderson hit me hard last week. I was his guest at dinner and we had some of these Limas, and I had to own up that as a tender, delicious bean they are unsurpassed. He knows of my partiality for tall Limas, but he assures me that while practical gardeners may share in my prejudice, the great majority of amateurs will not be bothered with poles, and many, now that they have got a dwarf form, will grow Limas, who before now wouldn't grow them at all. Our own dwarfs are in capital bearing condition, and very prolific, and still they are blooming and podding. And while Kumerle's Dwarf was a little shy at podding at first—no doubt on account of the incessant rainy weather—it is now bearing quite freely, also blooming and podding.

Queens County, L. I.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

THE formal manners of the last century seem both needless and absurd to us now, yet after all, an additional touch of ceremony would be rather an advantage to us. Just notice the average school-girl when she meets a friend on the street. It is "Hello Mame, where'r you goin'?" followed by the parting salute "So long." Now, some stilted, formal address would seem very much out of place, but not more so than these slangy, boydenish words. A girl cannot be too careful in her language, if she wishes to be regarded as a real gentlewoman. Rude and careless speech will infallibly lead to carelessness in manner.

* * *

A GIRL should be taught that she is to greet her schoolmates as well as her elders with a little bow and a pleasant, "How d'you do?"—such a salutation as, "Hello!" should never be permitted—except through the telephone. Nowadays we see a girl entering the parlor with a careless nod to her mother's callers. In the last century she would enter with a little courtesy to the inmates of the room, and then walking to the hostess or most prominent guest, would make another and a deeper courtesy. Very ceremonious it all seems, yet it was pretty and respectful.

* * *

READING the letters of a century agone one is more struck than ever with this ceremony. Mrs. Delany, writing to her mother when a middle-aged woman, began: "Honored Madam," and subscribed herself: "Your dutiful daughter and humble, obedient servant."

By the way, a most charming book to read aloud is the memoirs of this lady, "Autobiography and Correspondence of Mrs. Delany," published by Roberts Bros. She was an English woman of good birth, born in 1700. She died in 1788, after a long, busy and exemplary life. She was a woman of great culture, and during her long life made many friends of distinction. Her letters, chiefly addressed to a beloved sister, give all the current talk of the day—society, dress, and public affairs. One of her letters, addressed to a young relative, contains such excellent advice that it is as fresh and seasonable now as it was in 1774. She says; "Rise at seven, sacrifice to cleanliness in the first place; neatness of person and purity of mind are suitable companions; then, with awful attention, say your prayers, return thanks for the blessings you have received, and pray for their continuance, and for grace to make the best use of them..... I hope I need not recommend to you neatness and regularity in taking care of clothes, etc., keeping them in nice order and proper repair, *not depending* on its being *done for you.* Employ *two hours every day in plain work*, and *making up your* own *things*; it is an accomplishment necessary for every gentlewoman, and when *you* are in circumstances to make it less necessary or convenient, you will be better able to know when it is well done for you. But this is not to exclude, at their proper season, works of ingenuity: if you have learned to draw, give *one hour* to that each day, but *not* so as to interfere with what is more necessary. Bestow as little time on dress as possible, but let it always be neat, and suitable to your circumstances, (or position) and never *extravagantly in the fashion*, which is very vulgar, and shows levity of mind. Be assured that the only way to be beloved and happy, (even in a parent's house,) is to be humble, modest, attentive, and complying towards those who have taken you under their wing, adhering strictly to truth, and never *see* or *say* what is no business of yours."

Good sensible words now are these; one can hardly wonder that Hannah More wrote of Mrs. Delany as of one who "sheds a luster on our age."

OUT-DOOR STUDIES.

AS April passes into May the number of flowers claiming attention increases like a sum in arithmetical progression. A whole paper might be devoted to the violets, white, yellow, blue and purple. Deep in the woods rarer, shyer flowers are to be found; the Showy Orchis throws up its delicate spike of mingled white and lavender, and the Moccasin Flower gradually unfolds its rosy purple pouch. These two are representatives of the great orchid family, the most varied and curious class of plants we know. A majority of them are foreigners, but our own country gives us many species. The Showy Orchis—otherwise Orchis spectabilis—has two shiny, lily-like leaves; growing up from between them is a spike of oddly shaped flowers, the arched upper sepal of rosy-pink, with a tinge of purple; the lower part, or lip is white. "Preacher-in-the-Pulpit" is a common name for this flower, and it is more descriptive than popular names usually are, for the upper sepal suggests the arched sounding-board of a gothic pulpit in miniature.

The Moccasin Flower or Lady's-slipper, is chiefly noticeable for its odd, pouch-shaped lip. Our native species are not so noticeable for their resemblance to a slipper as some tropical varieties, which have given to the family its name of Cypripedium, or Venus's Slipper. The variety most frequently met with in the Middle States is the Stemless Lady's Slipper, which has a large pouch-like lip of rose-pink, sometimes tinged with purple. The lip is the most conspicuous part of the flower—not an uncommon thing with orchids—so that the other sepals and petals are quite insignificant. Occasionally the variety we are now discussing is very pale in color, sometimes pure white, and very dainty it is. It has a peculiarly rich, heavy odor, suggestive of strange tropic spices, which is also possessed in a less marked degree by the Showy Orchis. Less common than the Stemless Lady's Slipper is a yellow variety, the Downy Lady's Slipper, very charming with its clear golden color and velvety texture.

Botanical names are difficult to many; yet it is impossible to identify wild flowers by their local titles. Take, for example, the honeysuckle. When I say honeysuckle, I mean the twining shrub known to botanists as Lonicera. In many places the same popular name is applied to the wild azalea—pinxter-blossom, as it is called in New Jersey. Stranger still, the same name of honeysuckle is given to the wild columbine—aquilegia—which belongs to the Crow-foot family, and is not even a poor relation of the real, simon-pure honeysuckle. This columbine, which you will find on rocky hillsides in May and June, is rather eccentric in shape; its five petals with spreading lips terminate in long spurs, which some little imagination might turn into eagle's talons. The flower is scarlet, lined with yellow, and very showy. The compound leaves are very graceful, and altogether the columbine may be regarded as one of our handsomest wild flowers. Its English name is from some Latin derivative, meaning a dove; old botanists likened it to a flock of young doves feeding around a dish. Notwithstanding its beauty, this flower is dedicated by the old poets to folly and desertion, which Ophelia implies in "Hamlet," when she says:

"There's fennel for you, and columbines."

While another old dramatist takes it as the emblem of ingratitude.

Growing with the columbine one usually finds the little mountain pink, which is a country cousin of our garden phlox. It creeps along the ground, its fresh green leaves suggesting a moss, whence its popular name of "Moss Pink." Its bright rose-pink flowers make a glowing carpet on hillsides quite early in the spring, and it often keeps on flowering until late in the autumn. It is not really a true pink; it belongs to another natural order; though Wordsworth's description applies to our little phlox as well as to the true pink, or dianthus.

"The wild pink crowns the garden wall,
And with the flowers are intermingled stones,
Sparry and bright rough scattering on the hills."

We have another example of confusion worse confounded in common names; the little Houstonia cœrulea, as we must call it to be explicit. It is called "Quaker Lady," "Quaker Bonnet," "Innocence," "Forget-me-not," "Venus's Pride," "Dwarf-Pink," "American Daisy" and "Bluet." There, eight names to choose from; four pretty, but meaningless, and four inaccurate. It is not a daisy, or a forget-me-not, or a pink, or a bluet. The last name, which Prof. Meehan has adopted, really belongs to the Corn-flower. It is a little starry flower, faint blue or lilac, with a yellow center. It is extremely local in its habit; you may find it growing profusely in one meadow, and fail to discover it anywhere else in the same county. Properly, it grows in damp meadows, but I have found it in company with columbines on the rocks around Passaic Falls, N. J. It is really lovely, and there is little doubt that it would improve with cultivation.

Do you know the Painted-Cup? It is not uncommon, according to Gray, although I have met with it but rarely. It is somewhat hairy, with incised leaves, bright green. Its peculiarity is that the leaves around the inconspicuous flower are bright, vivid scarlet, giving the effect of a flower. It looks, to use an unpoetic simile, as if the top of the plant had been dipped into a pot of red dye. It is such a noticeable oddity that it will be recognized by this brief description. It is found flowering in low, sandy ground, from June to August. It is dedicated to Castillejo, a Spanish botanist, and has received the name Castilleia coccinea. It is a member of the Great Figwort family, to which our every-day mullein belongs.

Another member of the same family is the common Toad flax, or Butter-and-Eggs. We will call it Toad-flax, however, for the second name is also given in England to one of the daffodils. Our plant has a dense raceme of yellow flowers, with a queer resemblance to the mouth of a fairy-book dragon. It throws up a spike one to three feet high, and is very showy, but a most pernicious weed. It would not be a weed if we confined it to our gardens; but it requires that definition, because it is emphatically, a plant out of place; a different definition from that given by a precocious little girl—a weed is a plant you don't have to pay for.

COTTAGE MAID.

FEEDING THE BABY.

THE poor little babies suffer enough this warm weather; even when fed and treated aright, any carelessness or neglect may be really fatal to them. Among the many excellent suggestions given by the New York Board of Health is a series on the care of infants in hot weather, which needs no apology for its reproduction. It is as follows:

I.—NURSING OF INFANTS.

"Over-feeding does more harm than anything else; nurse an infant a month or two old every two or three hours.

Nurse an infant of six months and over five times in 24 hours, and no more.

If an infant is thirsty, give it pure water or barley-water, no sugar.

II.—FEEDING OF INFANTS.

Boil a teaspoonful of powdered barley (ground in coffee grinder) and half a pint of water, with a little salt, for 15 minutes; strain; then mix it with half as much boiled milk; add a lump of white sugar the size of a walnut and give it luke-warm from a nursing bottle. Keep bottle and mouth-piece in a bowl of water when not in use, to which a little soda may be added.

For infants five or six months old, give half barley-water and half boiled milk, with salt and a lump of sugar.

For older infants, give more milk than barley-water.

For infants very costive, give oatmeal instead of barley. Cook and strain as before.

When your breast-milk is only half enough, change off between breast-milk and this prepared food.

In hot weather if blue litmus paper, applied to the food, turns red the food is too acid, and you must make a fresh mess or add a small pinch of baking-soda.

Infants of six months may have beef-tea or beef-soup once a day, by itself or mixed with other food, and when ten or twelve months old a crust of bread and a piece of rare beef to suck.

No child under two years ought to eat at your table.

Give no candies, in fact nothing that is not contained in these rules, without a doctor's orders.

III.—SUMMER COMPLAINT.

It comes from over-feeding, and hot and foul air. Keep doors and windows open.

Wash your well children with cool water twice a day or oftener in the hot season.

Never neglect looseness of the bowels in an infant; consult the family or dispensary physician at once, and he will give you rules about what it should take and how it should be nursed. Keep your rooms as cool as possible, have them well ventilated, and do not allow any bad smell to come from sinks, privies, garbage-boxes, or gutters about the house where you live.

Where an infant is cross and irritable in the hot weather, a trip on the water will do it a great deal of good (ferryboat or steamboat), and may prevent cholera-infantum."

PATTY GARTON.

GOLDEN GRAINS.

THE following item is credited to Beecher, Lowell and others. It is too good to be lost. No man is born into the world whose work is not born with him. There are always work and tools to work withal, for those who will.....

TALMAGE tells this beautiful anecdote; One day a man was taking me from the depot to a village. He was very rough and coarse, and blasphemous; but after a while he began to talk of his little son whom he had lost. "O, sir," he said, "that boy was different from the rest of us. He never used any bad language; no, sir, I never heard him use a bad word in my life. He used to say his prayers, and we laughed at him, but he would keep on saying his prayers, and I often thought: 'I can't keep that child,' and I said to my wife; 'Mother, we can't keep that child.' But, sir, the day he was drowned, and they brought him in and laid him down on the carpet, so white and so beautiful, my heart broke, sir. I knew we couldn't keep him."....

SPEAKING of unworthy members of our church he said: "You will find worm-eaten leaves in Fontainebleau, and insects that sting in the fairy groves of the Champs-Elysees. You do not tear down and destroy the whole garden because there are a few specimens of gnarled fruit. I admit there are men and women in the church who ought not to be there;

REV. A. E. WINSHIP says, no youth however good or great may be his inheritance of faith, however regular his attendance upon family devotions, religious worship and Sunday school, is secure in his faith until he has had that training which shall enable the mind to weigh intelligently, honestly and devoutly all literary criticism of moral and religious truths.....

Domestic Economy

CONDUCTED BY MRS. AGNES E. M. CARMAN.

SOME ODDS AND ENDS FOR THE HOUSEKEEPER; COOKING TOMATOES.

A GOOD and thrifty housewife does not discard things as soon as holes make their appearance, but she sets about doing what she can to battle with Time's ravages. If tiny holes are found in table linen or garments, the first thing to do is to darn them neatly, selecting the number of thread or cotton best suited to the material to be darned, using also as *fine* a needle as possible. If the material is much worn, it is best to lay a piece of the same under the thin place and darn down upon it. This gives strength, but does not make so neat a job. A ragged tear must always have an extra piece laid under it. It is very hard to make a three-cornered tear, when darned, lie nicely, but if you begin such in the center, at the point, and darn towards the ends you will find that you can with care, succeed very nicely indeed. Dampen slightly on the wrong side (if it is dress material) and press with a hot iron, being careful to lay a thin cloth over the darn so that the heat from the iron will not discolor the goods. In this way the tear will scarcely be noticed at all.

Table cloths, (unless the holes are very small) should be patched when holes appear. First baste a square of the same material under the hole; next cut the edges of the hole even, turn under and hem down to the patch as neatly as possible. Then turn over the cloth and hem the patch to the other cloth in the same manner. This adds a neat finish to both sides and will lie flat when ironed. Always patch or darn before washing, or you cannot do it so well afterward, as the washing and ironing stiffen the edges. If the linen is figured or striped be sure to match the pattern. Calico and gingham should be mended in like manner.

If you find a hole in Balbriggan underwear or stockings you may fill it up neatly and prevent the break from spreading if you take a fine steel crochet needle and catch up the stitches that are coming undone, and then, with cotton that is suitable in thickness and color, crochet up the hole with a chain stitch. This looks neater than a darn—but if the hole is large, you may find it difficult to do—In that case a darn is necessary.

When your sheets begin to show unmistakable signs of becoming thin in the middle, do not wait till they are worn all to pieces, for then they will be of little use; but split them down the center, and overhand the two selvages together, thus putting the thin parts outside. Hem the sides. In this way your sheets will last a great deal longer, for the outside edges really get but little wear, and when turned will still be quite strong. But if you have some on hand that have become too much worn for this to be done, you will find that the outside edges will make good bolster cases—that is, if you still use the old-fashioned bolster. Save your old pieces of white muslin, for they make good dusters, and will be found very useful for cleaning windows, as they will be free from lint.

If you have a white skirt worn across the front below the belt, and perhaps a little frayed about the hem, you may mend it very nicely, by cutting the worn part off the hem, turning the two raw edges in and overhanding them. A rick-rack or crocheted edge sewed to this will entirely hide the fact that this has been done. A new yoke may be put around the top, or you may make a new top to the skirt, sewing the lower half on as one does with a "cut skirt," or a "French flounce."

When your table-cloths are worn out beyond mending, cut square pieces from the best parts of them, and hem neatly. They will make nice napkins for holding the children's lunches, or for the little ones to use at the table, for if they are stained or lost, your set will not be broken.

Tomatoes are very toothsome baked, stewed, fried, roasted or broiled, and make a delightful salad, either plainly seasoned with vinegar, pepper and salt, or with a Mayonnaise dressing. To bake them, select large, firm ones and cut a cavity in each where the stem grows. In this put a little minced onion, a pinch of pepper and salt, a spoonful of cracker dust and a generous lump of butter. Place in a deep pan and bake in a moderately quick oven.

To fry them, cut the slices thick, as the heat shrinks them, and, if cut too thin you will not be able to dish without having them break. Dip the slices into flour or cracker-dust and fry in butter. Your pan must be iron and *hot*.

If you intend having cold, sliced tomatoes, as a salad, take the necessary number and lay them on the ice about an hour before they are to be used. This makes them cold and hardens them. With a sharp knife peel the skin off and slice thinly. Dress to suit the taste.

To broil tomatoes, put them in a wire broiler and hold over a quick, clear fire. If placed in a hot iron spider (whole) and held over a quick fire they will have the appearance and taste of being broiled.

But of all the ways to cook tomatoes I am about to tell you the *best*. Perhaps you have never heard of it, (I don't believe you have), but do not let that deter you from giving it a trial, for I have never yet met anyone who had heard of it till I told her. Yet all who use this method usually gave up all other ways of cooking them. An old lady invented (if that is the proper word) it years ago and imparted her secret to me. I have told it among my friends and as they all like the mode so well I concluded to tell it to the RURAL readers as I count them among my friends. Well then, it is simply to *boil them*. Now I imagine I hear some one say. "Boil them! Why all the juice will run out and they'll be mushy!" But they won't be anything of the sort.

Select good firm tomatoes; drop them into a pail or pot of hot water and boil them the same as you would boil potatoes with their "jackets" on. The length of time of course, will depend somewhat on the size of the fruit and the quickness of the fire. When they have been boiling for about five minutes, try them with a fork. If they are soft all the way through they are done. Lift out, peel the skin off, add butter, pepper and salt. If you have any doubt on the subject, all I have to say is, *try it* for yourself and see.

Green tomatoes fried in the same manner as ripe ones are exceedingly good. They also make fine preserves and pickles.

DORA HARVEY VROOMAN.

A YOUNG girl about to start on her first journey alone, was told by her mother not to be made unhappy by any accident that might happen to her wearing apparel during her visit. A friend who heard the remark said that she thought it was such a comfort to a child, especially a sensitive one, to be told a thing of that kind when going away from parental care.

CANNING FRUIT.

AN experience of nearly twenty years in canning fruit, both at home and in commercial canneries, is my excuse for venturing into a discussion of this subject.

With many people canning fruit without sugar is a regular hobby. They claim that sugar destroys the natural flavor, makes the fruit indigestible, etc. I have never yet seen any cooked fruit that had a natural flavor, if by natural flavor is meant that of uncooked fruit. Strawberries, for instance, have a very decided flavor, but if canned without sugar, they are as near nothing as can be imagined.

I have become surfeited with natural-flavored fruit, and now I want it canned with plenty of sugar, and I'll take all risks of indigestion.

In canning berries the less water used the better the berries will be. If a few are pressed and the juice is used for cooking the others, the best possible results will be obtained. Cochineal is frequently used to give a good color to strawberries, but nothing under the sun, as far as I know, can give them a good taste.

I consider yellow peaches alone fit for canning purposes. I have never seen white or red peaches canned in a way to suit my taste. They are too insipid. Peaches properly canned should show clear sirup when opened. Soft peaches, improperly handled before canning will make a thick sirup full of floating particles. With firm fruit the sirup will be clear. If a can of peaches is opened and the fruit is firm and hard, while the sirup looks like muddy water, you can wager your bonnet that filth is the cause. For a prime article, take fruit fully ripe but not soft, prepare by hand, dropping each piece into water as soon as cut.

If glass is to be used, cook the fruit for a few minutes and can. If tin cans fastened with solder are used, the fruit may be scalded to make it pack closely, and packed with the fingers, sealed up, except a small hole, and placed for five minutes in boiling water to expel the air, seal up tightly and boil 20 to 30 minutes.

Tomatoes should be scalded, skinned, cut, and thoroughly cooked if glass is used. If tin cans are used, (and they are much better than glass), pack in the raw tomatoes as long as you can, pressing out all juice and seeds possible, and proceed as with peaches, except that it is better to boil them twice as long.

Corn and peas are very hard to keep by ordinary methods, and where one succeeds, 20 fail. Nevertheless, the method used by canneries in this section of the country is about as follows: The corn is husked and then passed through the cutting machines. Another machine removes all the corn silks, and the corn is packed into tin cans by hand. The cans are filled with hot salt water, sealed, heated and vented; the vents are closed, and the cans are finally boiled in a steam-tight kettle for about 40 minutes at a temperature of 245 degrees, more or less. The impossibility of securing such a degree of heat is the reason why there are so many failures in the household. Twenty years ago a dilute acid was used to secure the requisite degree of heat. Four or five hours' boiling sometimes will do, but oftener will not.

There is a good deal of nonsense believed in regard to the use of glass cans. Some people boil them before using; others place a silver spoon in each while filling, and a few use cloths wrung out of hot water wrapped around them. I use a dry cloth simply for convenience in handling the hot cans. By wrapping a dry cloth of any kind around each can, you can get a good grip on the ends and you can hold it any way and anywhere you want it while filling, and you can put it on a table or elsewhere without blistering your hands. Many people believe fruit put up in tins to be unwholesome, but I have never known of any injurious effects from it, and such fruit certainly is the better in taste. Where fruit is left in tins after being opened, no doubt its acids will amalgamate with the metals and form poisonous compounds. I have yet to see the first good tomatoes preserved in glass.

A MAN.

CURRANT juice, scalded (without sugar) and bottled to use with Spitzenberg Apples next winter "alf and alt" make a most delicious jelly. AUNT BETSEY.

News of the Week.

HOME NEWS.

SATURDAY, August 17, 1889.

WEDNESDAY morning, August 14, ex-Judge Davis S. Terry, 66 years old, but possessed of the strength and ability of 45, a dangerous Pacific Coast rowdy for a generation, was shot through the heart by Deputy United States Marshal David Nagle, at the breakfast table at the depot hotel at Lathrop, a town 85 miles from San Francisco on the Southern Overland Railroad. On the arrival of the train from the south at 7:30 A. M., Justice Stephen J. Field, 73 years old, of the United States Supreme Court, who had been holding Circuit Court at Los Angeles, and Deputy Nagle, passengers, were breakfasting together in the depot dining-room when Terry and his notorious wife Sarah Althea Hill, also passengers, came in. Last September Justice Field sentenced Terry to imprisonment for six months and Sarah Althea for one month for gross contempt of court, committed on his deciding against the validy of Sarah's alleged marriage with millionaire ex-Senator Sharon. On his release rowdy Terry who had been bitterly hostile to Field from early California days, openly threatened vengeance. For fear of the man, Attorney-General Miller, at Washington, had ordered Nagle to accompany Field to protect him from the male and female rowdies. On recognizing Field, Sarah at once left the dining-room to get a pistol from her reticule in the train, while Terry approached Field from behind and gave him a heavy slap on the face. He raised his hand to strike again, then Nagle, formerly city marshal at Tombstone, Arizona, and mighty quick with the trigger, shouted: "Stop! Stop!" and as Terry's fist was descending, shot him through the heart. Sarah soon returned and of course, virago-like, at once made a scene. Terry was born in Dodd County Ky., in 1823, went to California during the gold fever, was elected Chief Justice of the State Supreme Court when 33; was imprisoned for several months by the Vigilantes for stabbing one of them. Killed U. S. Senator David Broderick in a duel in 1859. Commanded a Confederate regiment in Texas during the war; was Democratic Elector in California in 1880, and the only one defeated. Since then has been notorious in connection with the infamous Hill-Sharon litigation before the State and Federal Courts in California, in which he was engaged in constant frays. General verdict: The State's well rid of him. The trouble isn't over yet, however, as virago and adventuress Sarah Althea still survives.....

The new Inman steamer City of Paris, which some weeks ago beat the record on western trip from Queenstown to Sandy Hook, has just beaten the eastern record also, having made an unprecedentedly quick trip between the two places in five days, 23 hours and 40 minutes, only 37 minutes more than her westward record. This is the first time the eastern passage has been made inside of six days. Several new flyers have just started to beat the City of Paris's time; others are on the stocks to outspeed all now built, and designers are racking their brains to plan others that will outstrip anything yet begun.

.....There are strong indications of the formation of an Earthenware Trust and a Table Glassware Combination. Earthenware is protected by a duty of 55 per cent., and glassware by one of 45 per cent.—a pretty good basis for successful combination.....

What little fighting has taken place lately in Hayti, has been against Hippolyte who has gone north, abandoning the Amazon-guarded precincts of Port-au-Prince. As a relief to last week's tragedy down there, comes the comical news that both sides have suspended fighting to get in out of the wet, as it has been raining very hard there too..... Some weeks ago it was discovered that Sherman Brothers of Buffalo, N. Y., by means of fraudulent ware-house receipts, had stolen $375,000 worth of wheat from the Buffalo elevators. Restitution to the amount of $200,000 has been made, leaving a balance of $175,000. One of the brothers has just been jailed, the other is in Canada.....The Minnesota dressed beef law was again declared unconstitutional last Tuesday—this time at Duluth, by State Judges Sterns and Ensign.

.....President Harrison has been having a glorious time of it up at Bar Harbor, where he has been visiting Secretary Blaine and several other notabilities, national and local. Next week he'll spend a few days at Indianapolis to lay the corner-stone of a soldiers' monument and attend a reunion of his old regiment. Persistent office-seekers, of course, detract somewhat from his enjoyment wherever he goes.....There's a marvelous religious craze among the negroes of the South. First a white impostor who proclaimed himself the Messiah, persuaded a number of blacks to crucify themselves and indulge in all sorts of outrageous performances in South Carolina. Then at the command of an old negro who calls himself the Prophet Daniel, three young negroes, last Saturday, to imitate Shadrach, Meshach and Abednego, rushed into a white-hot furnace of molten iron near Birmingham, Ala. To-morrow crowds of negroes will meet at church to see the cremated gulls appear as angels. The deluded blacks are doing all sorts of queer, wild, sad, horrible and ridiculous things.....

The estimated losses by fire at Spokane Falls have fallen from $15,000,000 to $6,000,000. The insurance companies will pay $2,500,000 of this. The price of real estate in the burned district has advanced considerably. It's hard to down the buoyant spirits of the mighty West..... Several doubles of Tascott the murderer of Chicago millionaire Snell, for whose arrest Snell's widow offers $50,000 reward, have been captured in several widely-separated places during the week; but the murderer's whereabouts is still a mystery to the most lynx-eyed Hawkshaw stimulated by so big a reward.....A number of Canadians have established an electric plant on the Canadian side of Niagara Falls, deriving their power from the falls. They propose to send "currents" into the United States to supply power and lights cheaper than these can be supplied by machinery driven by steam, and they have asked the Treasury Department, whether the electricity they propose to send to Buffalo and other places will be liable to import duty? Why not? Surely the electrical business is still an infant industry that needs "protection" as much as infant industries a century or so old....Poor Nevada! she has so many taxes she doesn't know what to do. With a population too slim for a prosperous Territory, she finds it a hard job to raise money enough to run a State Government..... ....Ex-Attorney-General Garland has become attorney for the Northern Pacific Railroad at a salary of $25,000 a year. The government of the United States paid him only $8,000 a year.....

Bombastes Furioso appears to be editing several Canadian papers, judging from their wild vaporings with regard to the disasters about to befall this country on account of seizure of the Black Diamond by the Rush. A prize crew of one was jocularly put on board the Diamond and he was ordered to take her to Sitka, capital of Alaska, where a United States Court could condemn her. As soon as she got out of sight of the Rush, her captain changed her course and made for Victoria, capital of British Columbia, where she arrived safely not a little to the merriment and satisfaction of all parties. Though there are probably not less than 50 Canadian and American poaching vessels illegally fishing for seals in Behring Sea, the Diamond has hitherto appeared to be the only capture made by the two United States revenue cutters cruising there. No doubt the seals thus clandestinely killed will transcend the Alaska Company's catch of $1,500,000 worth a year. Ex-Secretary Bayard wanted to place the seal fisheries under the protection of all the maritime nations—a policy much better for the seals and the seal-skin wearers too.....

Francis E. Spinner, the amiable owner of the celebrated hieroglyphic signature, is reported to be hopelessly sick at his home at Pablo Beach, Florida. Cancer in the face due to wearing a badly-fitting pair of eye-glasses, is the trouble.....Gov. Humphrey, of Kansas, on Wednesday, issued a call for that deep-water convention to meet at Topeka, on October 1. All the States and Territories west of the Mississippi are invited to send representatives. Can't have too many friends for such an undertaking in Congress.....

The general impression is that the recently purchased lands in the Sioux reservation will not be opened to settlement before spring. No crops could be raised this year and the sufferings of new settlers would probably be terrible during next winter; whereas all can have a fair start in spring. Gen. Crook says the number of Indians in the seven tribes on the reservation is not over 23,000, though estimates varied from 35,000 to 60,000. Sitting Bull and a handful of his followers are still malcontents, but helpless.....Dr. Brown-Sequard's "elixir" is being tried by doctors all over the country with very different results. As a rule it is found to act as a more or less powerful tonic and invigorator; but in some cases, it has produced little or no effect, and in several its effects have been more or less injurious, being very disastrous in a few. The effects appear to depend, in great part, on the age and condition of the subjects. They seem greatest where the patients expect great things, and least where they don't know what is being done to them. Hence imagination must play a big part in the "cures." It appears all-important that the "elixir" should be used in an hour or less after its materials are taken from the slaughtered animal; that the latter should be thoroughly healthy, and that the "elixir" and all the tools and vessels used in its preparation should be kept absolutely free from the taint of bacteria which are everywhere present. Many of the failures and injurious effects are attributed to carelessness in regard to these last points. As an "elixir of life" to restore youth, of course it's a humbug; as a beneficial tonic and invigorator, it may be a blessing. Several thousand people must now be undergoing experiments, and the real character of the "discovery" must soon be definitely known.....

AGRICULTURAL NEWS.

SATURDAY, August 17, 1889.

THE international show of live stock at Paris embraced a large section devoted to poultry, there being nearly 2,000 pens on exhibition. The greater part of these were entered by French exhibitors, there being a few American, and a still smaller number of English exhibitors. The Crévecœurs took the lead as is usually the case at a French show. The Houdans were poorly represented, and this breed is said to be losing in popularity. There were fine specimens of La Fléche, Courtes Pattes, and one lot of the Gray La Bresse. Of the foreign breeds, Cochins took the lead, but there were also specimens of Brahmas, Dorkings, Spanish, Andalusians, Minorcas, Langshans, Hamburgs and Polish. The American breeds were represented by Leghorns, Wyandottes and Plymouth Rocks. The French demand a white-fleshed fowl, so that the latter breeds are not likely to become popular. There were some turkeys, a few geese, chiefly Toulouse, and quite a show of ducks, principally Rouen and Pekins..... At a recent dairy conference at Ballston, N. Y., the cream from 200 pounds of milk from "native" cows with Jersey and Ayrshire crosses, made nine pounds of butter, or one pound from 22 1-5 pounds of milk. The cream from 200 pounds of milk from high-bred Jerseys, made 13.56 pounds of butter, or one pound from 14.74 pounds of milk. The Jerseys were pastured and fed grain; it was not stated how the natives were fed. It is remarked that the best dairymen attend these conferences, while the men who would be most benefited are conspicuous by their absence.....Georgia is said to have produced corn enough for home supply the present year. This has not been done before in 30 years.....Some of the implement dealers in the Northwest have been distributing binding twine made of jute and hemp to the farmers free of cost. It is said to give good satisfaction.....A stick of dynamite was fed into a thrashing machine in Indiana the other day. As an annihilator it was a success, as the machine hasn't been found since, and three men and two teams were killed..... Some experiments have been made near New Orleans in raising jute on alluvial land, which resulted in a growth 11 feet high, and a perfectly developed plant.....The value of agricultural implements exported from New York during June was $213,780. They went to almost every part of the known world..... ....The imports of sugar at Philadelphia are constantly increasing, a large fleet of sugar-carriers now being on their way to that port from the Philippine Islands. The imports will exceed those of last year by more than 20,000 tons, the increase coming chiefly from the British West Indies and Cuba..... The wool-clip of Montana this year is estimated at 9,000,000 pounds. It commands five cents per pound more than last year, or an increase of $450,000 for the season's clip..... The cost of exporting cattle from the seaboard to English markets is about $18.50 per head for freight, $4 for hay, grain and care, $2 for insurance, and $4 for commissions, selling, etc. The cattle must be slaughtered within 10 days after being landed..... The immense number of immigrants into the Argentine Republic is having its effect on the amount of corn exported. Last year 445,000 tons were shipped, this year the amount will probably reach 2,000,000 tons.... .....The wool-growers of Russia are now clamoring for a tariff on imported wool.....The Buckeye Mills of Marysville, California, have just made a shipment of 3,000 barrels of flour to Australia, the third this year. Large quantities of this flour are also shipped to China.. .....The Standard Live Stock Insurance Company, of Reading, Pa., was sold out by the sheriff lately. The concern had about $1,000,000 insurance on its books, but the only assets were a lot of old office furniture..... ... . First Comptroller Matthews has decided that the appropriation of $600,000 made by the act of March 2, 1889, for "agricultural experiment stations," can be used for the benefit only of the 40 stations for which estimates were made, namely: $15,000 each for stations in each of the 38 States, in the Territory of Dakota and at the Agricultural Department, and that no part of the appropriation can be used in the establishment of such stations in any of the Territories with the exception of Dakota, that being the only one included in the estimates on which the appropriation was based.....The Topeka, Kansas, sugar works burned, entailing a loss of $70,000.....A hairless horse imported from Australia is the latest equine curiosity in San Francisco ..... The first bale of the new crop of California hops has been received in the city, and is of excellent quality.... .....At a recent sale of Jersey Cattle in Missouri, 28 head were sold at an average price of $50 each. Either the quality of Missouri Jerseys is very low, or else prices are.....Prairie dogs have become a great pest in some parts of Kansas since their natural enemies the hawks and eagles were destroyed, and now the farmers want some method of exterminating the dogs. ..Longstreet beat Proctor Knott and Salvator at Monmouth winning the Omnibus Stakes. The mile was made in 1:44, the 1¼ mile in 2: 09¾.....The American Horse Show Association will hold its first annual show at Chicago, from October 30 to November 9. This show was formerly held in connection with the Fat Stock Show, under the direction of the Illinois State Board of Agriculture.....

Tired Nature's Sweet Restorer.

Sancho Panza, wasn't it? who cried "God bless the man who first invented sleep." And England's greatest bard has called it "Tired Nature's Sweet Restorer." Still there is another invigorating and refreshing element of existence which is also "Tired Nature's Sweet Restorer."

We call it Compound Oxygen; our patients through gratitude call it *blessed*.

No. 33 Main Street,
JAMESTOWN, N. Y., June 30, 1888.

Compound Oxygen has greatly benefited me. WM. H. PROUDFIT.

CENTER MORICHES, L.I., N.Y., July 15, 1888

I am better than I have been in eleven years. It is truly wonderful what Compound Oxygen will do. Mrs. J. F. PENNY.

MIDDLETOWN, MD., May 28, 1888.

I have been using Compound Oxygen for four weeks, and must say that it is one of the greatest medical discoveries ever made. Since using it my catarrh and hoarseness have almost entirely left me.

GEO. C. RODERICK.

We publish a brochure of 200 pages, regarding the effect of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia; all chronic and nervous disorders. It will be sent, free of charge, to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa., or 120 Sutter Street, San Francisco, Cal.—*Adv.*

Literary.

FARM LIBRARIES.

A SUCCESSFUL farmer of my acquaintance often says that he thinks one of the best habits a boy or girl can acquire is the reading habit, and he carefully promotes such habits in his own home by buying such books and papers as his children love to read, always taking care to direct them toward the best books and the most instructive papers he can find.

There is no doubt many another father who wishes to get the very best books for his family; but neither he nor they know exactly what the best books are, and so, buying blindly, books of less merit are purchased with money which would have paid for better works. What to buy must be determined, in part, by the years of an individual—rhymes and simple tales—true ones are always most relished—for the child at the knee; easy history, science and literature for the growing girl and boy, and by all means some good biographies of people of our own country, as Washington, Franklin, Lincoln. There is no objection to any good biography, but in a limited collection of books our own men should have a place rather than strangers. It is well, too, if possible, to allow for different tastes; one boy may be carried away by books on bugs and bats and squirming things, while another loves only stories of heroes and daring exploits. Probably, in either case, it would be better to induce the boy to read a little of something out of his preferred line lest he grow up wise on one side and ignorant on the other; but, whatever comes, it would be better not to put him out of the notion of reading, for it may be impossible, once out, ever to get him in the notion again.

After one has acquired a fair knowledge of general things, there is much to be said in favor of what may be called reading in a line *i. e.*, buying what one is able upon some one theme and reading upon that theme until he is familiar with all that has been written upon it, and this is especially a fault in farm libraries where the buyer is quite likely to buy only books treating of the farm, when, at the same time, he has a half dozen boys and girls starving for something just outside the farm, and a wife who snatches at every bit of poetry and sentiment that comes to her eye through the meager channels of the almanac or the country newspaper.

For general reading there are some books necessary to every household, first of all of which is the Bible; not the big, brass-clasped ten-dollar book always untouched on the parlor table and fit for the only use to which it is put, the stowing away of relics of all sorts, from the children's valentines to the sacred locks of hair; but the convenient-sized reference Bible for family reading and Sunday School work. The 10 dollars which are paid for the other useless lumber will supply a moderate-sized family with good Bibles and a concordance, and a little more money added will buy Deem's or Farrar's or Geikie's Life of Christ, any one of which is good, though I prefer Geikie. Then, second, get a dictionary, any standard one—Webster's is very good for giving definitions, the use to which it will oftenest be put—and, some rainy day, a little stand can be made to hold the book, which will do away with the greatest objection to it for home use, viz.; its size and weight.

After these two books add Æsop's Fables and Anderson's Fairy Tales for the children, and a book of Bible stories, if you can find one, and then a book or two that you know your wife loves. One cannot dictate here, for one woman loves one thing and another something else, but the husband can find out what to buy for his wife. If the wife potters lovingly day after day about a few pots or plants, ten to one she would be helped and delighted by a book on flower culture, and I know one woman in a backward Southern State who herself cultivates a plot of cotton to buy herself books on anatomy and physiolgy.

As to the husband, he, like the wife, chooses books according to his tastes: the fruit grower selects books on fruits; the stock grower books on stock growing, veterinary, and other subjects closely allied to his line of work. As a rule, the farmer is not a specialist, but has interests both in fruit and stock and grain and he wants a little help on each of these lines. For aids in fruit growing, there are numberless little treatises and collections, more, perhaps than upon both the other subjects, but a very good—probably the best single volume to own is Thomas's American Fruit Culturist, taking care always to get the best edition, which in this case happens to be the last. For vegetables there are also many books the best of which the specialist will know, but Joseph Harris's Gardening for Young and Old, or Peter Henderson's Gardening for Profit, will prove helpful, and these will prepare for other books if they are needed. In stock, there are so many kinds of stock one must know a little of a man's wants before he can answer intelligently, as the enthusiastic breeder of Jerseys could have little interest in a book upon Shorthorns and *vice versa*; or, if an exclusive breeder of horses or sheep or hogs, the cattle book would be of no value whatever. Compiled books of the cheaper class have long supplied the needs of the average reader, giving a scrappy information, possibly as much as was demanded formerly, but hardly as much as is demanded now, and there may be no better way for a man to find out just the best book for himself than to write asking information of some honorable man engaged in the same branch, or of a professor of agriculture in some agricultural college, or, better, of his agricultural paper. Another very satisfactory way would be for each one to buy several books and decide for himself which was best. For cattle, Allen's American Cattle, latest edition, is good; for cattle feeding, Armsby is perhaps the choice, but buy Stewart on Cattle Feeding and compare the two. They will cost no more than four dollars and a half, and they might make many times that amount in the difference in the value of stock fed by their methods. For pigs, Harris is a standard, and Coburn has written a good work on Swine Husbandry. Horses have innumerable works written upon and about them, but as the book most called for is a book for the treatment of diseases, I name Law's Veterinary Adviser as the most advisable single volume for the purpose, and it is also to be recommended for the treatment of other animals. Sheep have Randall's Practical Shepherd and Stewart's Shepherds' Manual. Randall has also a book on Fine Wool Sheep Husbandry, and Youatt, an old and popular writer, has a book exclusively upon sheep. If one wishes books upon bees or poultry he may buy Cook's Manual of the Apiary, Root's A, B, C of Bee Culture or any one of several other excellent ones, and Wright's Practical Poultry Keeper, Stoddard's An Egg Farm, or, Profits in Poultry and their Profitable Management.

Added to the above are books upon grasses and grains and miscellaneous works, which one will really need, but which it would be quite impossible to name in a short article; but what is to prevent any farmer from adding to his collection the much laughed at agricultural reports, and the reports of horticultural and other societies? They frequently cost only the stamps to pay the postage, and the United States Reports may be had for the asking, by addressing one's Representative in Congress. Some of the best agricultural literature of the day is published only in reports or in the bulletins of the new experiment stations of the States, and these last may also usually be had by any one who sends in his name and post-office address.

Suppose one's shelves are full of the literature of the farm, there still remains the great mass of general literature untouched, and the farm boy and girl would get up early in the morning for a chance to read the Pilgrim's Progress or The Arabian Nights, and the older ones will be glad of Shakspeare, Washington Irving, Longfellow, an English history—Knight's, perhaps, for the pictures, but Green's is excellent—some American history, some good novels, Hawthorne's Scarlet Letter, Thackeray's Newcomes, Dickens's David Copperfield, Miss Mulock's John Halifax, Scott's Ivanhoe, Wallace's Ben Hur, George Eliot's Middlemarch, and if there is any one in the family who loves a lovely child, Mrs. Burnett's Little Lord Fauntleroy. If to these could be added a little poetry from time to time, especially our American poets, Holmes, Lowell and Whittier, we should not have more books in the house than would fill out the long winter evenings, and we should not be guilty of having more books in the house than the reader could digest.

At the risk of going beyond the buyer's purse, I must say a word for an encyclopedia. It answers almost as many questions as a dictionary and answers them a great deal more fully. Johnson's is one of the best, price and all considered, and a new edition is just out.

A good way to increase a library is to bind the magazines and papers which come into the house; if one cannot afford the expense at present, a temporary binding made at home will hold them safely till one's ship comes in. Cloth is probably the most satisfactory binding of the cheaper sorts and half morocco with cloth sides is as good and handsome as need be for common work and is much to be preferred to either sheep or calf or Russia leather. A bad way to get a library is to buy of a traveling book agent who usually sells a poor class of books at a very high price. Some good books, like Grant's Memoirs, are sold only by agents, but these books are readily had of second-hand dealers at half of the first cost.

In buying books look at the print, paper and binding; if the print be blurred and defective, it will hurt the eyes to read it; if the paper be thin and grayish, the best print will not be readable upon it, and if the book open at the middle, and will not lie open on a table or flat surface, the binding is not well done and the covers and leaves will easily become loose. As a rule, avoid fancy prices, buying good print and paper in a suitable binding, which may be replaced when it wears out.

Colorado. M. J. CARPENTER.

GOLDEN ROD.

By the highway, in the meadow, on the hill-top, everywhere;
Golden rod is gaily waving brilliant banners in the air,
Such a host of tiny blossoms, grow upon one slender stem,
Making one rare combination, 'tis of the wayside flowers the gem.

Modestly it bends its blossom with its weight of burnished gold,
If it were the precious metal that its dainty petals hold,
For its rare intrinsic value, golden rod would then be sought.
All the memories clustering around it, would be lost in sordid thought.

Does the meaning name attract us; our cupidity awake,
Do we seek the golden flower for the glittering tempter's sake?
Nay! there's nothing in this flower to arouse our greed for gold;
No pecuniary value does the golden blossom hold.

For its meek and lowly bearing, rather than a haughty pride,
Do we love this favorite flower; for it flourishes beside
Humblest weeds, and barren places, of the earth it does enfold,
With an oriental covering, a gorgeous hue of gold.

Twining with the flowers of summer, golden glory of her crown,
Lingering still to deck the autumn, while the leaves are turning brown.
For their personal adornment devotees of fashion bend
At thy shrine; and beg thee humbly of thy golden crown to lend.

Golden rod, or Solidago, join, make firm, thy name implies,
In thy unity of beauty all thy wondrous secret lies.
Does not then this charming flower for us each a lesson hold?
In this plant we find a precept worth its weight in burnished gold.

CATALOGUES, ETC., RECEIVED.

CORNISH ORGANS AND PIANOS.—Circulars of the celebrated Cornish organs and pianos from Cornish & Co., Washington, N. J. The fact that this firm has numerous imitators both in Washington and elsewhere, is evidence of the excellent reputation and the superior quality of their instruments. Notwithstanding the increased capacity of their factory, they are kept busy night and day filling orders. Some of their offers are wonderfully liberal and we hope that every one of our readers will get their catalogue.

HARTFORD COMPRESSED AIR PUMP CO., BOUND BROOK, N. J.—This company makes a machine for utilizing compressed air to raise water. It is used in connection with a wind-mill. Its advantages are economy of power; several different pumps may be operated by the same wind-mill; it has no parts exposed to the weather to be clogged by sleet or snow; it requires no attention; it can be set at any distance from the source of water supply. Send for this circular.

CHAMPION EVAPORATOR, G. H. GRIMM MANUFACTURING CO., HUDSON, O.—This large and finely illustrated catalogue shows the various parts of the Champion Evaporator; the construction of the corrugations, the regulator, the portable siphon, etc., etc. It also contains much valuable information concerning the business of evaporating maple sap, sorghum, cider and fruit. In many localities this business might be conducted with profit. It is a matter worth looking into. An evaporator is often the means of saving a crop which would otherwise be lost.

BRYANT & STRATTONS CORRESPONDENCE COLLEGE, BUFFALO, N. Y.—Every farmer's son should know more of book-keeping and business correspondence than he can learn in the ordinary district school. It is possible to go through a course of study at home, which will be of very great value, and we would advise our young readers to send to the above address for circulars telling how it may be done.

THE PERKINS WIND-MILL AND AXE CO., MISHAWAKA, IND.—This is a beautifully colored village scene, showing the Perkins Wind-mill in operation. One can see at a glance the simplicity and mechanical perfection of these mills. The cut shows the three principal parts: the main casting, the wheel and the rudder. There are no iron weights, side vanes, governing balls or hooks or levers to mar the appearance of the mill and get out of order, and cause stoppage and inconvenience. Send for this circular.

DAIRY QUESTIONS.—Director Peter Collier, of the Geneva, N. Y. Experiment Station, is collecting some very valuable statistics regarding the dairy interests of New York State. He has sent out many copies of the following list of questions. We hope our New York readers will help the work along by answering them fully. Are there any who cannot answer them satisfactorily? Perhaps it would be fairer to ask if there are any who *can* answer them?

SUMMER EXPENSE FOR COWS.

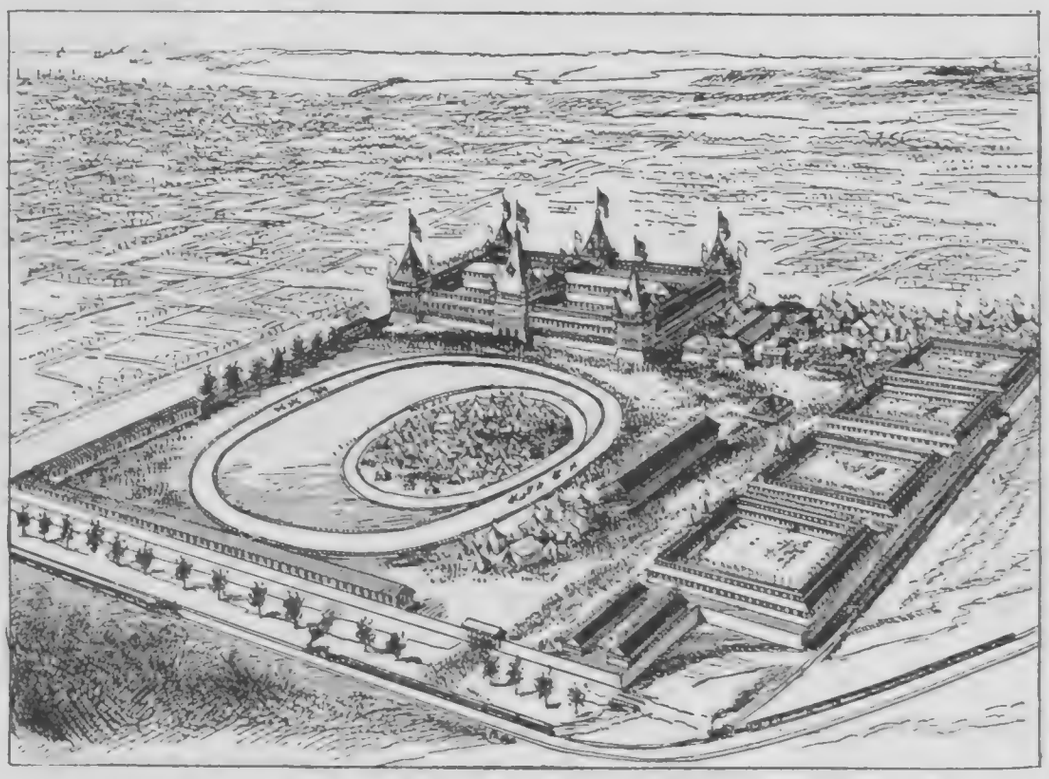
ANALYSES AND VALUATION OF COMPLETE FERTILIZERS.—Bulletin 56 from the New Jersey Experiment Station. This pamphlet contains analyses of 73 different brands of complete fertilizers that are offered to New Jersey farmers. Of these 40 contain more of each of the plant food elements than the manufacturers claim. "Cary's Pure Dissolved Bone," selling price $45 per ton, was found to be worth $2.89 per ton, while "Excelsior No. 1," from the same party, selling at $40, was worth $2.42. Yet considerable quantities of these fertilizers are still bought by New Jersey farmers. Prof. Cook gives the following general suggestions:

"It is admitted by most farmers that fertilizers pay; how to buy and how to use, are questions which are becoming clearer each year. Yet the large number of brands from which to select is at times confusing to those who are influenced by names of brands and prices per ton. The fact that any brand reaches its guarantee in contained plant-food, or that it corresponds closely in estimated value to selling price, is not evidence in itself that it is better than some other brands which do not reach their claims in this respect. In addition to these points, the guarantee must be high enough to warrant the price, and the contained plant-food must be the kind that is needed. Attention cannot be too often called to the fact that nitrogen, phosphoric acid and potash are the elements sought for in a complete fertilizer; the amount, kind and quality of these determine its commercial, and to a large degree its agricultural value. As a rule, the fertilizer which contains the greatest amounts of these elements is the cheapest; for the cost of manufacture, freightage and rate of commission are the same for high-grade as for low-grade fertilizers, and the labor on the part of the farmer is increased as the grade of the goods decreases."



GROUNDS OF THE BUFFALO INTERNATIONAL EXPOSITION Fig 216.

CREAM BY MACHINERY.—Catalogue of the De Laval Separator Company, 74 Cortlandt Street, New York. The history of the separator is now pretty well known. It is a wonderful machine and thousands are now in use. This catalogue tells all about the machine and also gives considerable dairy information.

NOXIOUS WEEDS OF WISCONSIN.—In Bulletin No. 20, Prof. E. S. Goff writes on the above subject. In 1885 the legislature of Wisconsin declared certain weeds outlaws, and ordered the authorities to kill them at sight. Prof. Goff gives a list of these weeds, with illustrations, and the story of their habits. We shall have more to say about this matter later.

THE HORN FLY.—This insect is dignified by the publication of a bulletin devoted to his habits and tastes. Special bulletin F. of the New Jersey Station gives the fly the best possible send-off. Little seems to be known about him except that he likes to work at the base of the horns on cattle. Tobacco insecticides are most effective against him.

Indust'l Societies.

THE BUFFALO INDUSTRIAL FAIR.

THIS appears to be an era for the holding of large fairs at permanent locations. It seems as though the plan of holding State or sectional exhibitions at a new place each year, so that all sections may be represented, has gone out of fashion. The advantages claimed for a permanent location are many and strong, and if we may judge from the recent actions of fair managers, the arguments are convincing. The Buffalo International Exposition is an illustration of the modern idea. Last year, its first season, there was an attendance of 400,000 people, and this year's attendance promises to be even larger. At Fig. 216 we give a view of the grounds used by the Buffalo Exposition. The buildings are all elegant and substantial, and the grounds are excellently arranged for exhibition purposes. The fair will be held this year September 3—10.

Miscellaneous.

A JERSEYMAN'S JOTTINGS.

THE POTATO ROT.—This is still the main topic of interest with our farmers. We are now getting hold of the matter and can get some idea of the damage. I expect to lose just about one-half of my crop, and I think that will be a fair statement for most of New Jersey. We shall lose even more than that if we get more of these heavy showers followed by hot, scalding suns. Reports from other parts of the country are conflicting. Here is a letter just received from Central Indiana.

"You speak of damage to the potato crop, East. We have the largest crop for three years. We have much rain too, but potatoes out of sloughs are a large crop. I never before had 10 or 12 large potatoes in a hill in *drill* planting; generally three or four. I may have 1,000 bushels on five acres. We usually have about 100 to 135 bushels per acre."

Other letters from Ohio and Michigan tell a mixed up story. I still think there will be a short crop, though I notice the Department of Agriculture still goes merrily on predicting a "fine crop." This Indiana man certainly has no cause to complain this year. I think his prices will be satisfactory. A great many Michigan potatoes come to this market. The chances for the Michigan crop this year seem to be below the average.

A POTATO BULLETIN.—The New Jersey Experiment Station people are so alarmed about the rot that they have issued a special bulletin telling all they can about the disease. We all know pretty well how the vines and tubers look, and also the sort of weather most favorable for the spread of the rot. Mr. Halsted seems to think that coarse barnyard manure helps the rot along, particularly in seasons like the last, I think there is something in this. I wish other farmers would tell us what they think about it. This may be one reason why farmers always want to use fertilizers on the potato crop. In this bulletin we are advised to dig the potatoes as soon as we can. This advice ought to be qualified. On dry ground, I think the tubers are just about as safe in the soil as out of it.

I shall not dig my potatoes until about the usual time for digging. There are some fields near my place so wet that a man can hardly get in to dig. This shows what a very wet season we have had. I feel rather sorry for the potato-digger men this season, There could not be a worse time to show off the merits of their machines. Quite a number of our scientific men are telling us to spray the potato vines with the Bordeaux Mixture on the first appearance of the mildew that attacks the vines. They don't tell us how to do it or whether we can put our Paris-green into the mixture and thus make one application for beetles and rot. I fear sometimes that many of these scientific people never saw a good-sized potato field, but confine their operations to one or two plants.

Miscellaneous Advertising.

LISTER'S

Agricultural Chemical Works,

SOLE MANUFACTURERS AND PROPRIETORS OF ALL BRANDS OF

Lister Brothers' Animal Bone Fertilizers

Principal Office and Works at Newark, N. J.

The following well-known and very popular Brands of Fertilizers are offered to the Trade:

Standard Phosphate, Ammoniated Dissolved Bone, Harvest Queen, Potato Fertilizer, —LISTER'S— Corn Fertilizer, Celebrated Ground Bone, Tobacco Fertilizer.

These Fertilizers are Guaranteed to be Made from Animal Bones, and not from Phosphate Rock.

J. W. Sullivan, Agent, Monrovia, Md.: LIBERTYTOWN, Frederick County, Md., April 4th, 1889

I have been using "Lister's Standard" on my wheat land for the last eight or ten years. Previous to tha time I used *good fertilizer*. I have for many years kept an accurate account of my yearly yield of wheat Since I commenced using the "Standard," I find by careful calculation that my yield of wheat has increased fully 50 per cent. I regard "Lister's Standard" as the most reliable fertilizer I have ever tried, and, of course, will use no other so long as it is procurable at a reasonable price. Yours &c., D. W. HAMMOND.

BOOMING!!!

Yes, that's the only word that will express it. We did more business last month than any month since our existence. We have been almost rushed to death with orders, in fact we have actually got behind, and are now compelled to still further

ENLARGE AND IMPROVE OUR MAMMOTH WORKS

and the end of this month will see us in better shape to fill orders than any factory in existence.

We think we hear you say, "What remarkable success the "Murray" people have had," and we say in reply, there is nothing remarkable about it. We simply started out to do an *honest, straight-forward business*, to sell our "Murray" Buggies and Harness solely on their merits & low prices; to *stick to the people* and not to the **POOLS AND TRUSTS** which are only to *"Enrich the Rich"* and *"Impoverish the Poor."*

By the **Latest Improved Machinery, Skilled Workmen** and **Long Experience** in the **BUGGY AND HARNESS** business, we are enabled to put the **"MURRAY"** Goods on the market at

PRICES THAT DEFY COMPETITION. SOME PRICES THAT TALK.

BUGGIES!

If you value your money, don't buy elsewhere before seeing our Catalogue.

$15.00 for one of the best Road Carts made

$55.95 for either a Side Bar or End Spring Murray Buggy

$108.00 for our Murray Canopy Top Side Bar Surreys

$109.00 for our elegant Jump Seat Surrey

We're not afraid to show our prices, for we know they can't be beat.

! ! $66.90 ! !

We're the only Factory in the U. S. that **CAN DO THIS!!!**

Just think, sixty-six dollars and ninety cents for a "Murray" Brewster Side-Bar Top Buggy, and a set of "Murray" Single Strap Track Harness. It seems strange, but it's true, and we are the only Firm that can do it.

HARNESS!

If you want the Best and Cheapest, buy of us.

$5.95 for our No. 1 Murray Single Buggy Harness

$9.85 for our No. 2 Murray Single Buggy Harness

$10.95 for our No. 3 Murray Single Buggy Harness

$15.20 for our No. 4 Murray Double Buggy Harness

$19.80 for our No. 5 Murray Double Buggy Harness

Remember, that every harness that leaves our factory is made of the best No. 1 OAK TANNED LEATHER.

HONEST GOODS, LOW PRICES and **COURTEOUS TREATMENT TO OUR CUSTOMERS** is our motto.

Call and see or write to us for our Catalogue and Price List. No middle men between us and the consumer.

TICKS

Hon. JOHN E. RUSSELL, of Massachusetts, says of THYMO-CRESOL (the Cold-water Dip): *"It will stimulate the skin, increase the growth of the wool, and destroy all parasites. I would not be without it if it cost $10 gallon. It is the best thing for sores of any kind."* Non-poisonous. Safe in coldest weather. Imported only by LAWFORD BROS., Baltimore, Md. Sample by Mail, 50 Cents. Mention this Paper.

THE OLDEST MEDICINE IN THE WORLD IS PROBABLY

Dr. ISAAC THOMPSON'S

CELEBRATED EYE-WATER.

This article is a carefully prepared physician's prescription, and has been in constant use for *nearly a century*. There are few diseases to which mankind are subject more distressing than sore eyes—none, perhaps, for which more remedies have been tried without success. For all external inflammation of the eyes, it is an infallible remedy, and for safety and efficacy it has never been equaled in removing ophthalmia or inflammation of the eyes at the commencement, and in curing chronic cases from defluxion of sharp humors. If the directions are followed it will never fail. We particularly invite the attention of physicians to its merits. For sale by all druggists.

THE RURAL NEW-YORKER

A JOURNAL FOR THE SUBURBAN AND COUNTRY HOME

VOL. XLVIII NO. 2066 NEW YORK, AUGUST 31, 1889. PRICE FIVE CENTS, $2.00 PER YEAR.

[Entered according to Act of Congress, in the Year 1889, by the Rural New-Yorker, in the Office of the Librarian of Congress, at Washington.]

Floricultural.

A ROSE BUSH—PLEASANT VALLEY, CALIFORNIA.

IN Pleasant Valley, four or five miles from Vacaville, in one of the best fruit regions of California, Mr. E. K. Thurber owns extensive orchards. It is a region of great beauty, with grand oaks in the valley, and well-timbered mountains sheltering the warm hill-slopes where the earlier fruit grows. The very first fruit that goes from California to New York is raised in this locality. The illustration, Figure 218, shows a rose vine which covers an arbor in Mr. Thurber's garden; a magnolia tree shows partly at the right, and the Vaca hills are in the background. The rose is from a single stem, some 15 years old, and entirely covers a large arbor. If I remember correctly, it is a large white climber, either the old Devoniensis or the La Marque, and its size and long blooming season make it notable in the valley. It receives no irrigation. Mr. Thurber is a prominent member of the California Fruit Union, and a very enterprising horticulturist, who has introduced many new varieties of fruit in the Vacaville district, and has originated several promising varieties.

SEXES IN THE CASTOR-OIL PLANT.

THE inflorescence of the castor-oil plant, the arrangement of the male and female flowers and the way in which pollenation is effected, are curious and interesting. In the corn plant the male flowers are borne upon clusters of slender spikes, which we call the tassel. Below, growing from the axils of one or more leaves, is the female flower in a many-rowed spike having a very long, slender pistil called the silk. The male and female flowers are thus separated all the way from two or three to 10 feet, according to the variety planted and the fertility of the soil. Corn pollen is quite heavy so that when ripe and being shed it will fall from the tassel directly down upon the silk, if there is no air stirring to waft it elsewhere. It often happens, depending upon the variety of corn and the season, that the silk and tassel do not mature at the same time. Sometimes the pollen is ripe before the silk appears outside of the husk; sometimes the silk is receptive before the pollen is mature.

In such cases a given plant must depend upon pollen from some other plant or plants, or we shall have grainless cobs. Or, in case of a deficiency of pollen, the cobs will mature only those kernels the silks of which were pollenated. Probably insects have very little to do with carrying the pollen from the tassel to the silk. The wind accomplishes this most effectually.

Now let us examine the castor-oil flowers. The illustration, Fig. 219, page 575, is accurately drawn from nature. It shows two racemes, in different stages of maturity, of hybrid plants produced by crossing Ricinus Africanus upon R. Gibsonii last year. The prickly-looking flowers at and near the top are the female flowers, each with its red plumous, two to six-parted stigmas. The male buds resemble in shape grains of buckwheat, producing as they bloom the roundish, fine, floury masses of anthers, as shown. Lowermost upon the left raceme are two male buds just opening, as if they were strawberry flowers just setting. An inch or so above is a single male flower in full bloom. On the right raceme are one male bud just breaking open and three in full bloom. It will be seen that the male flowers are *below* and the females on *top*, just reversing the position of the sexes on the corn plant. How is it, then, that castor-oil flowers bear such an

A ROSE BUSH, PLEASANT VALLEY, CALIFORNIA. From a Photograph. Fig. 218.

abundance of fruit? Do the female flowers depend upon insects to supply them with pollen? or must they depend upon the wind to waft it up to them at the right time?

During the past month or more the writer has watched the flowers at different times to ascertain. When the air is dry and the sun shines brightly the anthers are bursting every instant. One sees a little cloud of dust, as large as a pea perhaps, that reminds him of the distant discharge of a gun. A puff of smoke is readily seen, but there is no report. This castor-oil pollen, unlike corn pollen, which is inclined to fall, rises like a puff of smoke in a still atmosphere, at length enveloping the stigmas of the pistils immediately above it. This alone would suffice, it would seem, to pollenate the feathery stigmas. Many little insects, however, were noticed gathering the pollen from the male blossoms, and occasionally they would fly to the female blossoms in their further search for food.

In botany flowers in which the anthers and stigmas do not mature at the same time are called dichogamous. They are either protandrous or protogynous. In the first the stamens are developed before the pistils as, *e. g.* geraniums, pelargoniums, many of the compositæ, umbelliferæ, labiatæ, etc. To this category the corn plant may be added as a rule, with exceptions as above noted. In the second stigmas are receptive before the anthers are matured. Botany will have to originate another specific name for the sexual development of the ricinus. We have as we write, two racemes before us. On one the fruit (resembling horse-chestnut burrs) is more than half grown while the male flowers below are for the most part immature. On the other raceme, the male flowers are far advanced while not a fruit has formed.

Farm Economy.

PASTURING MEADOWS.

WHAT ABOUT THE PRACTICE?

ECONOMICAL OR WASTEFUL?

CONDITIONS THAT DETERMINE.

AN INTERESTING DISCUSSION.

FROM C. S. RICE.

I practice the pasturing of meadows, fully believing that by so doing more profit is realized than by any other management. The oft-repeated assertion of the agricultural press that meadows ought not to be pastured has little weight with me when compared with facts within my own observation and experience. For 20 years my meadows were not pastured, but the aftergrowth failed to keep up the yield of hay or to insure against the necessity for plowing and reseeding. I was led to change my practice while in pursuit of some method whereby my cows should have plenty of suitable food every day in the year. With a large amount of land devoted to pasturing, there was often a lack of milk-producing feed during the latter part of summer and autumn. Just the other side of the pasture fence in the meadow was plenty of the best of feed at the very time when the pasture failed to keep the cows from shrinking in their milk and becoming unprofitable. I began pasturing the newly-seeded clover and Timothy meadows with the expectation that they would be damaged and would have to be plowed and re-seeded in a year or two. The result was that the cows were carried through the critical period without shrinking and their year's productiveness and profit greatly increased and, much to my surprise, the meadow was in no way damaged. Now for 15 years my meadows have been regularly pastured. The amount of land used for pasture in the ordinary way has been greatly reduced and the area used for cultivated crops increased to the same extent. A meadow that will yield from two to three tons of clover and Timothy hay when cut the first of July, will in three or four weeks have a second growth eight inches in hight and will then afford excellent pasturage for the dairy. If judiciously pastured, it will produce a large amount of feed through the fall without being fed closely or in any way injuring the meadow, and the grass will finally go under the snow in a greener condition and in a better state of vitality than when allowed to make a more mature growth and then decay. The feed should be taken when in the best stage of growth and not be allowed to come to any sort of maturity. This is better for the cows and better for the meadow. I have but very little inside stationary fence on the farm, and to secure the after-feed when at its best I have provided more than 100 rods of portable fencing. This can be quickly set up or removed. The first cost was but little, and the fencing will last many years.

My meadows have not needed reseeding as often as they did under the former management, but they have steadily increased in the average yield and for several years very little has been plowed up because of failure to produce a fair crop. Several times in the last few years a meadow that would have yielded two tons of Timothy to the acre has been plowed only because the land was wanted for the better paying crops of fodder corn and potatoes. On the farm of 130 acres I had, three years ago, 70 acres of meadow and very little of it needed reseeding. Five acres were plowed for corn-fodder and ten acres that would have cut more than two tons to the acre, were turned into pasture, and some old pastures were taken for cultivation, and reseeding. The remaining 55 acres of meadow yielded an average of more than two tons of hay to the acre. My farm is not a natural grass farm, and, when this is taken into account, it does not look as though pasturing the meadows had ruined them.

I read in a leading agricultural paper recently an article by a well known writer in which he objected to pasturing meadows because the grass would be eaten and the weeds left and the land become full of weeds. Now I have a piece of meadow that was mowed this year for the fourth crop. It was pastured when newly seeded after the grass was high enough to hide the grain stubble, and it has been well pastured each year since. I have several times during the season taken well-known farmers to this field to show them the thick, perfect stand of clean Timothy. On a recent drive of ten miles among good farms I looked in vain for an equally thick, clean, even field of Timothy, and yet I know of no farm in this vicinity where meadows are so thoroughly and systematically pastured as on my own. With a short allowance of pasture, a little clover cut and fed in June, a few peas and oats in July, with plenty of corn-fodder and good after-feed through August and for the rest of the season, one cow can be made to yield as much net profit as two or three limited to old pasture and a little fodder corn. Cows that are in the best meadow after-feed will if good corn-fodder is drawn into the field, eat alternately of each, resting awhile occasionally and will if so fed keep up an even flow of milk through the season and will come to winter-quarters in prime condition for milk or fattening.

Pasturing, if done as it should be, brings the grass to the winter in much the same condition as though it had been mown three or four times during the fall. If the second crop is allowed to attain full growth it is not as valuable for feed as it is under continuous cropping, nor is it as well for the future crop of hay.

But some one will say: "Why not cut and cure the second crop for hay?" Well, it would require considerable labor and the weather is quite uncertain late in the season, and meadows well managed will fill the barn with hay at one cutting, and, finally, it is utter folly to be forever trying to secure more hay to winter cows that are but half supplied with suitable food the rest of the season.

I know that I am advocating the unpopular side of this question, but have had the best evidence before me for years that my practice of pasturing meadows does them no injury, and is of great benefit to the dairy.

Lewis County, N. Y.

FROM C. F. OLMSTED.

FROM my experience and observation, I think it is no economy to make a practice of pasturing our meadow lands after mowing. The damage is in exposing the roots to our severe winters. I think that we, as a rule, make our mowing machines cut too closely, and what grows after mowing, generally should be left for the winter protection, instead of allowing the stock to eat it off. Our winters of late have been severe on meadows as well as on grains, from the fact that there have been so much freezing and thawing, and unless the meadows have been protected by the "after-growth," the hay crop has been very perceptibly shortened. This has been most noticeable on what we call our "heavy" soils, or those soils where drainage is not so perfect as it should be, and with Timothy more than with the other grasses. There are cases where probably no harm would be done, especially in wet seasons, where the meadow had a heavy crop, or where it is so situated that the grass grows quickly, but then these meadows I think should not be pastured too late. Most of us are anxious to turn in the stock where the meadows look fine for feed, but it would be a better plan, if we would only do so, to give the meadows a good top-dressing after mowing, with either barnyard manure or some commercial fertilizer, instead of feeding them off.

Darien County, Conn.

FROM PROF. A. J. COOK.

I have always pastured my meadows after mowing, except in case of heavy clover, when I usually save this for seed. My land is clay loam, and is manured heavily once in four years. Unless I permit it to be eaten too closely or turn stock on it too early in the spring, I see no special harm in pasturing it. Of course, any vegetable thrives best when the balance between root, stem and leaf is not interfered with. We know that we can kill even Quack Grass and Canada Thistles by constantly cutting off the tops. Thus we may conclude that we can never cut off the green herbage of any plants without in some measure injuring the same. This shows why close pasturing is so harmful, and why all pasturing is expensive. We now know that we must allow our corn to advance to the drying off stage before cutting it for silage, would we secure the greatest returns. The larger the plant the more the working tissue, and the greater the work done, or the growth. We see then why pasturing is not good economy, and why close pasturing is ruinous to our meadows.

Ingham County, Mich.

FROM JOS. WOOLWORTH.

I do not think the practice of either pasturing or mowing a second crop of grass in the

Fig. 220. Page 575.

least injurious except in so far as it exhausts the soil. If it is good economy to take off the first crop, it is good also to take off the second, only we must feed the meadow well with some good commercial fertilizers or yard manure, as most convenient, only if one has to buy one or the other let him by all means use a commercial fertilizer as it is much the cheaper all things considered. In my opinion there is one serious objection to leaving the aftergrowth to be mowed into the next year's crop: it would render it very much harder to mow.

I am not aware that the nature of the soil would make any difference, yet it might. Mowing the after-growth is allowable under all circumstances provided the yield is large enough to pay. If one has good fences, let him pasture if he likes, but he shouldn't build fences to enable him to do so, it would be decidedly too expensive.

Hampden County, Mass.

FROM E. H. COLLINS.

I have never grown Timothy. It is as exhaustive to the soil as a corn crop; while clover is a blessing in every possible way. I cut clover one year and break it. Last year I had English Clover; this year I have Alsike (20 acres). The latter made the finest clover hay I have ever seen—about two tons to the acre. Both of these clovers give but one crop, so that I could pasture if I preferred. I used to do so, but a neighbor who did not pasture aftermath had a very lively fine soil on breaking the sod; while mine was rather harsh and cloddy, and his soil remained mellow all summer, while mine would harden in spite of cultivation. I attributed the difference to the greater amount of aftermath which he turned under, and to the fact that his stock did not tramp the land when wet. Harris in his "Talks on Manures," page 157, tries to demonstrate by experiment that clover mown twice for hay contains in its roots only half as much nitrogen as that cut once for hay and then for seed. The result is shown to be similar when clover is pastured as when it is cut for hay, and no doubt the

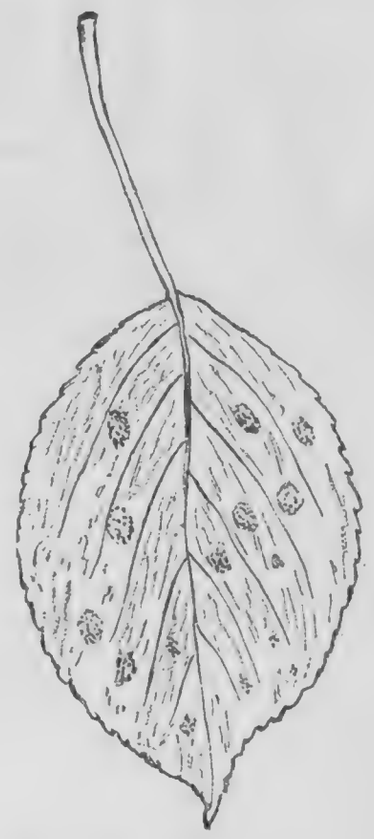

Fig. 221. Page 575.

plant matures a much larger, stronger root when not checked by cropping.

Hamilton County, Indiana,

FROM H. B. SPENCER.

To those who have devoted their land to raising grass for the purpose of making Timothy hay, the subject of the preservation of their meadows is of great importance. The labor of properly draining, enriching and preparing the ground for a permanent Timothy meadow, makes it for the interest of the owner that it should last in good condition for several years. My observation leads me to think that a rich, well-drained soil is the most natural for Timothy, and that if water stands around the roots in winter the crop is apt to die out, and what is left will rise up and form into bogs. The root of the Timothy plant is composed of little bulbs and roots, which multiply and increase from year to year, if the conditions are favorable. By cutting the grass about the time when it is in bloom, it is considered that the choicest hay for market can be made, and by so doing the bulbs too from which others sprout out and commence to form for another year's cutting, are properly matured if the conditions are favorable. To keep the bulbs and roots in a fresh and growing condition, should be the aim of the person who has a Timothy meadow.

To pasture such a meadow with animals that eat the leaves as fast as they appear, would weaken the roots so that they would be likely to be killed out in winter, especially if the ground is clayey and the soil thin and undrained. The amount of damage that pasturing a meadow would do could be determined only by dividing a given meadow and

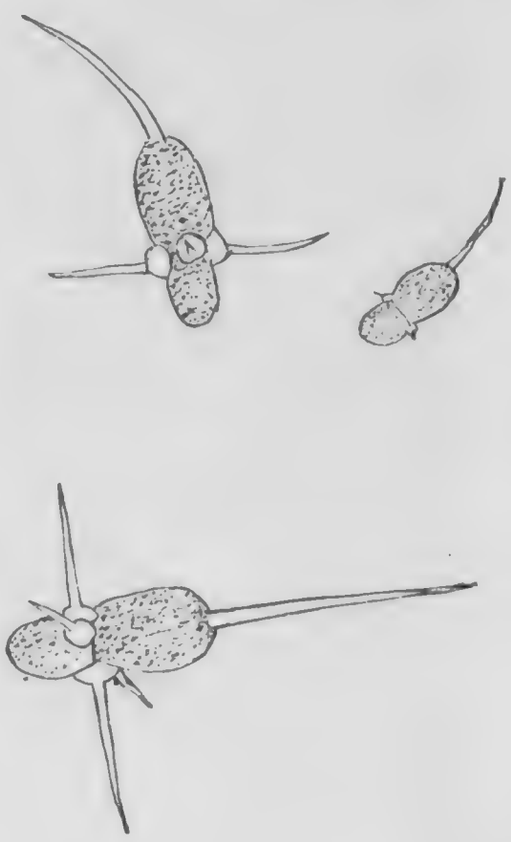

Fig. 222. Page 575.

giving each part the same treatment, with the exception of pasturing one and leaving the

other to make as large a growth as it would, and then noting the result in the succeeding crops. There are other reasons why the leaves of the grass should not be eaten closely, and one of these is the protection which they afford to the grass in the winter. The leaves hold the snow, and keep the grass from sudden changes in freezing and thawing. Therefore the practice of pasturing Timothy meadows cannot be commended; and the only exception that I know of, would be in case the soil were very rich, and the grass making too luxuriant a growth, so that the plants would be likely to smother each other and make too much dead grass in the succeeding crop; in such a case it might be judicious to pasture lightly in the fall; but not to the extent of leaving the ground bare. That there are other reasons why Timothy meadows die out, besides pasturing, I have no doubt, such as great drought, insect ravages, etc., which cannot be prevented by the farmer. But to preserve meadows, let the grass grow as much as it will after cutting it for hay, without pasturing.

Cuyahoga County, Ohio.

FROM PROF. I. P. ROBERTS.

This subject, notwithstanding all that has been written upon it, requires careful consideration, for if we get one dollar's worth of pasture this year and lose two dollars' worth of hay the next, we are greatly to blame for not learning our business. As a rule, most meadows should not be pastured after mowing. If a liberal amount of fertilizing material be applied after mowing, or in the spring, then fertile meadows may be pastured without injury. Contrary to the usual practice, we pasture our meadows, when we have any, the same as our other grass land, but never very closely or when the ground is wet. The effect of pasturing and fertilizing meadows may be illustrated by our practice this and last year. In 1887 we sowed a 16-acre field with wheat, and through a misunderstanding, about four acres were seeded to Timothy immediately after the drilling of the wheat. The following spring the whole field was seeded to clover, but the Timothy had such a start on the four acres referred to, that but little clover grew. Last year the field was mowed and afterwards pastured. This year the part producing clover was put into corn, and the Timothy was saved. Early in the spring, 200 pounds per acre of a mixture of equal parts of cotton-seed-hull ashes, cotton-seed meal and superphosphate were sowed. The hay, nearly all Timothy, was cut July 9th, well cured in the shock, and drawn in and weighed on July 11th and 12th. The area, when measured, proved to be 3.85 acres, and the yield of hay, 12 tons 190 pounds, or 3.14 tons per acre.

Grasses, like other plants, want an abundance of food. Whether we pasture and then fertilize, or whether we do neither, depends largely on conditions. Meadows on dryish, thin uplands, should not be pastured under any circumstances, because they receive no manures, the plants are weak, thin on the ground and require the winter and spring protection from cold and drying winds, which the aftermath gives. Orchard Grass if cut early, is often benefited by pasturing, while Timothy suffers most, Blue Grass or Redtop not so much. Meadows on low, rich lands, if old and too thick in the bottom to produce a fair length of grass, may often be pastured severely with benefit to them, provided they be thoroughly harrowed and treated with a dressing of ashes and cotton-seed meal or an equivalent, early the following spring. Remember that pasturing does not mean pulling the plants out by the roots, or eating off the crowns or filling the field with cow tracks. I do not believe that under ordinary circumstances it is economy to fertilize land with grass and clover, except incidentally. Cut or use the grass and clover, feed both with a liberal grain ration, at a profit, then return to the field all the voidings, which will contain more plant food than did the clover and grass. Plants were made to feed animals, while manure feeds plants.

Ithaca, N. Y.

FROM E. D. DOUGLAS.

The pasturing of meadows after mowing is a matter to be determined by their condition after each succeeding crop has been removed. In this, as in most departments of farm practice, no definite rule can be given, which will apply to all soils, seasons, and conditions. Where, however, there is but little aftermath, either in consequence of drought, or the poverty of the soil, it may be safely adopted as a rule that it should never be removed. On meadows where a judicious system of farm practice has been applied, the aftermath, with an average amount of rainfall, will be so heavy that its removal will become a matter of necessity; otherwise it will smother vegetation, and ruin the succeeding crop. There are two ways of accomplishing this removal: one by mowing, and the other by grazing. Experience has taught me that the latter is the better practice with judicious management. The removal by the mower, near the surface of the ground, of rapidly growing crops, like clover, is a severe strain upon their organism, which we might reasonably expect would seriously affect their vitality, and practically, I find this to be the result, while the more gradual, and less complete removal by grazing, is much less, if at all injurious.

In grazing, stock should never be allowed upon meadows until the aftermath is sufficiently grown to protect the stubble, nor should they ever remain late in the season, or crop too closely. There must invariably be enough aftermath left upon the ground to protect the roots from frost and hold more or less of the snows of winter to furnish additional protection. This is an indispensable condition of success, especially upon clay soils, as such soils are more readily disintegrated by frosts, and the roots of their vegetation are more subject to destruction by its action, than upon most other soils. By observing these conditions, we may secure much better results by grazing than by the use of the mower. The amount of damage resulting from mowing, or too close grazing, will depend much upon the character of the succeeding winter and spring, being much greater when the season is followed by an open winter than when the fields are well covered with snow.

A large proportion of the mowing lands here in Vermont, are what may be called "permanent meadows." They are seldom plowed, and only manured by the droppings of the animals allowed to range upon them, sometimes even in spring. In my own practice, I cannot afford to hold meadows in that condition, even without such irrational grazing. Nor do I believe that others can, unless it be in exceptional cases, as on river bottom lands or on those too far away to admit of the application of stable manure, or too rough to admit of renovation by plowing.

Such management ordinarily results in a bad mechanical condition. Many meadows having soils rich in plant food, fail to produce well, only because they are permanent meadows, and, for this reason, their soils have become hard and impenetrable. This state of things should be changed by the use of the plow and clover, and the feeding ground of their vegetation should be extended downward. We may thus also protect it from drought, from the brick-like condition in clay soils produced by excessive moisture, and from upheaval by frost. Meadows may often thus be made even without the application of manure, to produce an aftermath which will require removal. Neither can I afford to hold fields of arable land in permanent pasture. Experience long since taught me that, with an intelligent rotation of crops and a system of farming by which the plant food produced, both in a liquid and solid form is saved, and judiciously applied, old pastures may be made to yield not only abundant crops of hay, but as much pasturage after the hay crop is removed as they had previously produced during the entire season

The question, then, with regard to pasturing or not pasturing our mowing fields, depends much upon our farm management. The farmer who maintains a good mechanical condition in his soil, and who feeds his crops well, may successfully pasture his meadows after mowing. He who sells his hay, or wastes his manure, will not ordinarily be troubled with an excess of aftermath, and should not pasture his meadows. With such management the aftermath which is produced, should be allowed to remain, not only to furnish protection to the sward, but also as a source of plant food.

Male and Female Flowers From Nature. Fig. 219. See first page.

Pomological.

THE CRACKING OF PEARS.

PROF. BYRON D. HALSTED.

The disfigurement due to a minute fungus; effects of its attacks upon the leaves and fruit; formation of propagating spores; tentative remedies recommended; preventives.

The pear crop will be small in some localities this year. In many orchards the leaves have already fallen from the trees and the fruit, of about half size, is cracked so badly as to be entirely worthless, as at Figure 220. There are many persons who are satisfied to attribute this bad state of things entirely to the weather; while others believe that some other cause must be sought. A wet season doubtless has much to do with the prevalence of the trouble, but there is a fungus that constantly attends the peculiar premature dropping of the leaves, as witnessed the present season. To those who have studied into the habits of the fungus and related forms that prey upon other trees there is no reason to doubt that the prime cause of the loss of the crop is a minute fungus.

This fungus attacks the young leaves and fruit and after growing for a time, it makes itself known to the careful observer in small, discolored spots which often are of a carmine red, especially when upon fruit that possesses a blush at maturity. These spots are indicated in the engraving of a diseased leaf, Figure 221, and also in the cut of the badly affected fruit. When the leaves of a tree are badly infected they curl more or less according to their thickness, and drop from the stems leaving the trees leafless. The fruit is not affected in the same way, and at the present time it is not unusual to find trees loaded with fruits and without any foliage to feed and protect them. To have the leaves fall prematurely would be sufficient in itself to injure if not ruin the crop. But in this case the same fungus that preys upon the leaves also makes a home in the green flesh of the fruit and therefore with lack of nourishment, due to the defoliation and the disorganizing effect of the parasitic fungus, there is little wonder that the fruit becomes cracked and otherwise misshapen and dwarfed and worthless.

In the center of each leaf or fruit spots beneath the epidermis produce a multitude of small, peculiarly-shaped bodies, three of which are shown in Fig. 222 in different stages of development. These spores, when mature, find their way to the surface of the infested part and are carried away by winds and in other ways. Upon some badly infested pears upon my laboratory table these spores have worked their way to the surface and stand as minute white tufts all over the dark carmine epidermis. As they are continuously formed in a shallow cavity the mature ones are raised up out of the hole in the epidermis by the development of the younger ones. They are somewhat complex in structure; that is, they do not consist of a single smooth sac, but of a number grouped around each other in a uniform manner and are armed with bristles which probably assist in their dispersion. The matter of spore formation is dwelt upon here, for these bodies correspond to seeds in higher plants and a knowledge of their presence in large numbers helps materially to explain the rapid spreading of the trouble through an orchard. The horticulturist and farmer cannot be too strongly impressed with the fact that the various fungous diseases abound in the reproductive bodies called spores. Rusts and smuts, for example, so far as the external and therefore visible parts are concerned, are composed almost entirely of spores. It is, however, the fine threads of the fungus and not the spores, that do the bulk of the mischief to the host plant, and this destructive work may be far along before any sign of spore formation is to be found. The spores are for the farther spread of the fungus during that year or for carrying it over until the next season.

The fungus of the pear causing the leaf-blight and cracking of the fruit is not a new enemy, but was discovered many years ago. It has borne several botanical names, but the one by which it is now known is Entomosporium maculatum, Lev., a liberal translation of which is, a fungus with insect-like spores that produces spots.

What to do to prevent the development of this pest is the most important subject. It is essential to know the nature of a disease before rational treatment can be administered; but the existence of a disease whose nature is well understood, but for which there is no remedy, is of course possible. When such is the case, preventive measures are the only ones. With the pest in question the investigations with fungicides have not gone far enough to warrant the recommendation of any particular course of procedure. There is abundant work in this direction for the experiment stations, and if something effective and inexpensive can be found to ward off this discouraging blight to the pear industry, it will prove of inestimable value to horticulturists and all others.

The disease does much of its damaging work upon young trees while in nursery rows, and it may be of great importance that the fungus be attacked there, especially upon the young stems, and if the young trees can be cleared of it, a long step will be taken toward freeing the orchards. It is hoped that next year pear growers will feel inclined to test the value of a number of mixtures some of which have proved effective in checking the ravages of the black-rot—Anthricuosa, etc., of the grape. It is probable that a compound of sulphate of copper and lime, if sprayed upon the trees early and often enough, will prevent the spores from germinating and thus save the foliage of the trees. The same sprayings would hit the flowers and initial fruit and thereby prevent the pears from becoming infested and disfigured. It is certainly time that something should be done. The work of testing for the purpose of finding a variety proof against the fungus is not direct enough. From a large number of reports it is evident that the disease is very general and not altogether constant; that is, a variety may suffer much in one place and almost escape in another. If the Kieffer and Lawrence are less subject to it, who wishes to discard all earlier and better sorts for these? This fall burn the diseased leaves and worst fruit, and next spring spray thoroughly with the hope of a crop.

ORCHARD NOTES.—A limited amount of rainfall is a benefit during the blossoming of fruit trees, as it apparently destroys a fungus that attacks the young fruit. During apple blossoming time, we had this year delightful weather, and most varieties of apples were destroyed by this fungus when about the size of Marrowfat Peas. In the experiment of sprinkling a tree during the period of blossoming, the leaves were healthier and also what little fruit set was sounder than on the unsprayed trees. There is an evident difference in the appearance of the apples where the trees have been sprayed for the coddling moth. They are fairer and not so wormy. It looks as though spraying for the coddling moth will pay. Vicar Pears were badly affected with the fungus, although there are plenty of fruits left on the trees. The Wealthy Apple keeps its reputation for bearing, ripens here in September and is a high September apple. It is not of high quality and ripens when apples are plentiful and prices low.

Everywhere.

RURAL SPECIAL REPORTS.

THE POTATO CROP.

Colorado.

LONGMONT, Boulder County, August 17.—The condition of potatoes is good. There is no rot and potatoes are very rarely troubled with it. The acreage is 15 per cent. less than in 1888. The outlook is fair for an average yield. C. C. C.

Connecticut.

LONG HILL, Fairfield County, August 14.—Potatoes in this section are hardly worth digging; nearly all the large ones have rotted. Will have about one-quarter crop. Some varieties rot worse than others. With me the Early Ohio suffered terribly, while the White Flowers were nearly all sound; for Hebrons and Roses, rot is no name. R. N.-Y. No. 2 shows no signs of blight; they are a perfect potato. G. M. B.

BRIDGEPORT, Fairfield County, August 20.—About one-fifth of the potato crop is rotten, and about three-fourths of an average crop remains. D. H. W.

Illinois.

AURORA, Kane County, August 17.—The potato crop in this section is a full average I think. No rot that I have heard of prevails; the tubers are fine and worth 20 cents per bushel. I have heard that the crop was rotting up north and also in the southern part of the State, but I have nothing reliable on the matter. D. V. S.

WAUKEGAN, Lake County, August 16.—The potato crop is first-rate (100 per cent.) tubers very large and of good quality. There is no rot at present; if the weather keep dry for a week or two they will be safe from rot. C. W.

KANKAKEE County, August 18.—There is an immense crop of choice potatoes in this immediate vicinity and so far I have heard no complaint of rotting. Prices are very low owing to the systematic canvassing of our town by peddlers, causing a light demand at the grocers'. Early varieties are mostly grown. I dug one hill yesterday from an outside row and got 4½ pounds of monsters (a late variety), and I dug two hills of the same to-day and got over 6½ pounds from both; three of the tubers weighed four pounds. I plant one foot by 32 inches and according to the RURAL trench method. G. O. G.

Indiana.

GREENSBURG, Decatur County, August 15.—This is not a potato raising county. Large quantities are shipped in every year to supply the market. Foreign potatoes will often sell at twice the price of home-grown. The potato crop though was never better here than this year. They are of large size and excellent quality. They are sold to the stores now at 25 and 35 cents per bushel. W. O. F.

Iowa.

DES MOINES, Polk County, August 17.—There is no rot among potatoes, though the crop is badly damaged by grub-worms. Most farmers have dug their early crop and there is not more than half of an average, while the quality is poor. The late crop is hardly up to half an average, though favorable weather for three weeks may make quite a change for the better. Grubs are bad in this crop too. F. S. W.

DOW CITY, Crawford County, August 16.—The potato crop is good here. Frosts in May injured the crop on bottom lands; but the upland crop is good and the average will be fully up to that of former years. J. B. P.

Kansas.

EDWARDSVILLE, Wyandotte County, August 16.—Potatoes here are not rotting. The crop is a strong average, as to yield, and the acreage is slightly in excess of that in any former year. Early Ohio is mainly grown. More acres of potatoes are raised here than of corn and wheat together. E. T.

Maryland.

OAKLAND, Garrett County, August 15.—The condition of potatoes in our neighborhood is very poor owing to excessive wet. They are rotting and the flea-beetle has destroyed the foliage, which adds greatly to the short yield. There will be scarcely one-half of an average crop. H. W.

EASTON, Northampton County, August 15.—The Irish potato crop in this county is always small both in the number of acres planted and in the yield per acre. This year much of the seed of the early crop rotted in the ground. Where the stand was good, very light land yielded fairly. Elsewhere the potatoes rotted badly both in the ground and after they were dug. The fate of the late crop, planted from June 15—30, is yet uncertain. There has been very little trouble from the Colorado beetle this year. C. F. E.

Minnesota.

BRECKENRIDGE, Wilkin County, August 17.—Owing to a very dry summer, potatoes in this locality are a very short crop. Prices are high. Of course, none are rotting; but I think we will not have over one-half a crop. H. E. B.

New Hampshire.

SOUTH PITTSFIELD, Merrimack County, August 17.—Blight or fungous growth first appeared on potato vines three weeks since and it was confined to no one locality in the State and strong fears are entertained that it will soon reach the tubers. The unusual combinations of cool, dry weather will retard the growth of fungus. Not one per cent. of the small portion now harvested is diseased. The crop would have been above the average but most vines are now dead and less than a-half crop is the probability. Coos County is the great potato-growing region and the prospects of an average crop there are very poor. G. R. D.

NORTH HAMPTON, Rockingham County, August 16.—We are barely getting two-thirds of a crop of potatoes. Of this amount 20 per cent. have rotted. Potatoes are now being sold at 50 cents per bushel. G. E. T.

New Jersey.

PENN'S GROVE, Salem County, August 19.—This has been a poor year for farmers and truckers in this section. The grass crop was good; but was badly damaged in the making. Early potatoes, scalded early on high ground, and rotted late on low ground, and the late crop is badly damaged by the heavy rains. Watermelons are almost a total failure; many patches will not yield 25 good melons to the acre, and some not one, the vines having been dead for two weeks. The early tomato crop was short and the late crop bids fair to be the same. Many patches have been scalded, and on the best the latest sets have fallen off. Sweet potatoes look fair, but there cannot be a full crop, and if the prices rule as low as they have ruled for the last four years many truckers cannot make their expenses. Farms that have been offered for sale in this section the past three years have found slow sale, and if the prices and crops continue as poor in the future as they have been in the past few years, few farms will change hands except at very low figures. E. G. B.

New York.

COXSACKIE, Greene County, August 17.—As for my own potatoes, the Early Beauty of Hebrons are on a sandy soil and I find no rotten ones; there is an extra good crop; but my Rural Blush are on ground not so dry, and a little clayey. They are an extra crop but are rotting somewhat. My neighbors all find some rotten tubers. The crop is extra good all about here; but we have had so much rain and it is so warm between the showers that we expect to lose some by rot. There have been very few dug yet; only enough for use, as nearly every farmer is still working in the hay field. We generally expect to finish haying about July 25th, but here is a record of the last five weeks: during the first week there were two days—Monday and Saturday—and during the second week, five days, which gave us a chance to get in most of our oats; during the third week no one about here had a team harnessed; during the fourth week there were two dry days—Monday and Tuesday—and during the fifth week, which closed to-night—we had Monday and Friday and Saturday without rain, so you see that we have had a hard time for gathering hay. Corn about here is generally very poor. J. H. L.

BURNT HILLS, Saratoga County.—Not many potatoes dug as yet; yield not good; on low ground a complete failure; about one-third rotten on upland I should judge. Vines of late potatoes all dead. About the usual acreage planted; ground very wet at present. J. H. T.

BATAVIA, Genesee County, August 15.—Our potato crop is showing the first, or commencement of blight, to quite an extent, in the tops though it is possible with favorable weather following, not to lose the tubers to much extent by their rotting, only their quality and farther growth are said to be much affected. The weather is now cooler and drier, giving hopes of escaping a disastrous failure. H. I.

DEER PARK, Suffolk County, August 15.—Potatoes are rotting in this vicinity, but to what extent I cannot say at present as but few have been dug. Of the 60 or 70 bushels that we have just dug there was only about one bushel of rotten ones. D. C.

CUTCHOGUE, Suffolk County, August 14.—There are very few pieces of potatoes here that are not rotting. Few of the farmers have begun to dig as yet, so it is hard to tell what damage is done. As the vines were killed so early I should not think we would have more than half a crop. L. W.

KINGSTON, Ulster County, August 12.—Best authorities agree that the loss from rot is fully 50 per cent. Many fields will not be dug at all. H. H.

BATH, Steuben County, August 17.—Potatoes are rotting very badly; not over one-third of an average crop will be realized. Some people are intending to dig soon on account of the rot. Potatoes promised a good yield and fine quality until struck with the blight. G. M. D.

APULIA, Onondaga County, August 16.—Potatoes are all blighted and are rotting. Early Rose are not worth digging and Blush are commencing to rot; they look now as if they would not be over one-fourth of a crop. I planted one bushel of the Rural No. 2; I have not discovered any rotten ones in them yet. All potato vines never looked better before the blight struck them. Farmers are all discouraged over this year's crop. E. G. W.

GREENWICH, Washington County, August 16.—Potatoes are rotting badly. Some fields are struck with rust; vines dead. Prospect now is there will not be over one-half the usual crop. It is a little early to predict to what extent the rotting and rusting will lessen the crop. T. G. S.

CLYDE, Wayne County.—Early potatoes are rotting badly. The tops of late ones are dying. All the indications point towards a very light yield—probably less than half an average crop. B. W.

CORTLAND, Cortland County, August 15.—Farmers in our county are fearing rot much since the appearance of the blight. It is too early yet to make an estimate intelligently on the extent of an apparent loss. I think we can calculate on about two-thirds of an average yield. M. R. W.

Ohio.

HUDSON, Summit County, August 17.—Potatoes are rotting some, but I cannot yet say to what extent. In some places blight of some kind killed early ones too soon. Some report heavy loss, others but little. Late potatoes are also dying too soon. It is a good deal of a guess yet; but I doubt whether this locality has over half of last year's crop per acre planted. T. B. T.

WELLSVILLE, Columbiana County, August 15.—Potatoes are rotting some in the ground, I cannot tell to what extent yet, but do not anticipate anything serious. There will probably be an average crop, as potatoes are looking fine at present. F. P. L.

PLYMOUTH, Richland County, August 16.—As far as I can learn potatoes are somewhat better than an average crop. No rot as yet, but we have had a little too much rain. J. B.

WINONA, Columbiana County, August 14.—There was a large acreage of potatoes planted last spring but excessive wet weather causing weedy patches, together with a very large crop of Colorado beetles and flea-beetles will shorten the crop considerably. Prospects now for about two-thirds or nearly 75 bushels per acre. Prices are low. W. W.

Pennsylvania.

JUSTUS, Lackawanna County, August 15.—Owing to the wet season not more than two-thirds of the usual acreage of potatoes has been planted. We hear complaints of their rotting, but do not know to what extent it will affect the crop as it is too early to form any opinion. There certainly will not be more than one-third of last year's crop in this locality. G. W. G.

FRITZ TOWN, Berks County, August 19.—I judge about one-quarter of the potato crop is rotten already. If the rot keeps on at this rate it will probably take half of our crop in this neighborhood. S. S.

KNOX, Clarion County, August 17.—Potatoes are rotting badly. Some patches are hardly worth digging. I am safe in saying that the crop in this section will not be half an average crop. I have planted five different kinds of the leading varieties and see no difference as to rot. B. F. K.

Vermont.

SOUTH NEWFANE, Windham County, August 19.—I have made a personal examination of my own fields and have inquired of my neighbors as to theirs. On August 2nd, in this vicinity growing potatoes came to a dead halt, the tops all turning black and the leaves dropping. On moist or wet land the tubers are rotting badly but not much on dry or sandy land. One-half of an average crop was grown and 10 per cent. of these were rotten, giving us to-day about 40 per cent. of an average crop. As usual, my potatoes will remain in the ground, except what we use in the family, till it is decided whether they will all rot. If it prove safe to dig them I shall put them in the cellar the same day. S. M.

VERNON, Windham County, August 16.—But few potatoes are dug as yet; more acreage than common planted, those on dry upland are not rotting any yet, where planted on lowland and on clay soil, they are rotting some. The worst field that has been dug, (clay soil) had one-fourth spotted. Taking the increased acreage, I think there will be an average total amount in bushels. So much wet weather a few farmers not done haying yet. No wheat raised; rye and oats sprouted in field, damaged one-half; corn looking well, bidding fair for more than an average crop. E. P. J.

Wisconsin.

WATERTOWN, Jefferson County, August 17.—Potatoes are more than an average crop, the best for many years. I have not heard of any rotting. Probably they will be very low in price here this fall. J. M. C. F.

GREEN BAY, Brown County, August 15.—We have experienced an unusually cool and dry summer in this vicinity, very favorable for the growth of potatoes, but the late drought had ripened potato vines prematurely, which will bring it to an average crop, otherwise a crop far above the average would have resulted. No rot has been noticed so far, and will not appear unless we get very damp and hot weather before harvest. G. E. T. K.

PORTAGE, Columbia County, August 13.—Grain is all harvested and mostly stacked in this part of the country. Spring wheat is badly rusted, winter wheat and oats *good*; corn is growing finely, but will need all of September without frost to give an average crop. Stock of all kinds, excepting sheep, very low; stockers and feeders from $1.50 to $2.25 per cwt.; this includes butchers' cattle. Milch cows from $18 to $25 per head; hogs from $2.50 to $3.80 per cwt.; store sheep from $1.75 to $3.00 per head. A. E.

THE FARMER'S CLUB

ANSWERS TO CORRESPONDENTS

Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see if it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

WIDE-TIRED WAGONS.

Several Subscribers.—What advantages are claimed for wide-tired wagons? What is the additional cost of the wide tires? For what purposes are the wide tires mainly used? Would it pay a farmer to have two sets of wheels, one wide and the other narrow-tired?

ANS.—These questions have been referred to a number of manufacturers, and also to some farmers who have used the wide tires. The following answers give all the information we have obtained. If any of our readers have anything more to offer, we shall be pleased to have them send it along.

FROM THE KING & HAMILTON CO.

The difference in cost is from three to eight dollars according to the size of tire. Wide tires are good for sandy or soft roads. They don't sink so deeply or rut so badly. On soft roads wide tires are the lightest draft; on hard roads or with empty wagons we consider narrow tires best. We consider narrow tires best on hillside. We do not consider wide tires suitable for all kinds of road.

Ottawa, Ill.

FROM S. W. CHAPMAN.

I sell a three and a-half-inch tire, low-wheeled wagon, three feet two inch and three feet six inch wheels, which gives better satisfaction for farm use than any other wagon I sell for these reasons: They do not cut up the meadows or the roads, and are better adapted for use on the farm, because they are lower and easier to load with hay, manure, etc. They do not fail in any particular. It would not pay a farmer at the present low price of wagons to have two sets of wheels, for I am convinced no farmer would use any other wagon for farm purposes than these trucks if he once used them, unless he had teaming to do on bad, rutty roads. The proper thing for our supervisors to do would be to reduce every farmer's road tax, who would use a three and a-half-inch tire on his wagons. Then we would have better roads in Illinois.

Elgin, Ill.

FROM THE MITCHELL & LEWIS CO.

The difference in cost of broad tires is $5 per inch. The advantage of broad tires: In sandy roads the wheels will not sink so deeply, making draft lighter. The draft on a hard road is about the same as a narrow one, possibly a trifle more, as they present a greater surface for friction and resistance. Broad tires are better in sand, narrow on a hard, hill road; in mud a narrow felloe will hold less mud, therefore we think it is preferable. The broad-tired wheels on wagons are getting into favor more and more every year They are certainly better for the roads as they do not cut up the road nearly as badly as the narrow tires. Speaking from a manufacturer's standpoint, we would prefer to make the regular, narrow-tired wagon, as there is less detail about it, unless a certain width could be universally adopted all over the country. This would certainly be a great thing for keeping the country roads in good condition.

Racine, Wis.

FROM M. J. SNIVELY.

Wide-tired wagons are mostly used as farm wagons and with three to four-inch tire. A team can draw a heavy load over soft ground where a narrow tire would sink down with the same load and leave the ground in bad shape. In hauling hay, grain and manure a wide-tired wagon is preferable at all times. When a farmer has but one wagon, it will pay him to have two sets of wheels, as it takes but little time to change. Farmers in this section usually have two wagons: one with narrow, and one with wide tires; the narrow tires are used for road purposes, and the wide tires can be used on the road equally as well, provided all wagons have wide tires. As most of the road wagons are narrow-tired, in the spring season when the roads are soft, they plow up the roads with deep furrows and make it harder for a wide tire. If all wagons were wide-tired we would have much better roads, and I think the day is not far distant when wide-tired wagons will be used exclusively.

Stark County, Ohio.

FROM THE E. D. CLAPP WAGON COMPANY.

The difference in the cost between the wide-tires and the regular width is at the rate of $1.20 per ¼ inch. The advantage claimed for wide tires is that in soft ground they do not cut down like narrow tires which, of course, makes a difference in the draft of the wagon. We should think the narrow-tired wagon would run easier in the mud and a wide-tired one would run easier in the sand. We do not think broad tires are used to any extent on the roads unless the laws of the city or county where they are run compel it.

Auburn, N. Y.

FROM BRADLEY & CO.

As we make light work exclusively, the subject of the width of tire does not come up in our business. To give you an idea of what the people of Syracuse think on this subject, we would say that there is an ordinance making it a misdemeanor subject to fine to draw heavy wagons over our paved streets with narrow tires. All wagons here used for delivering building stone, brick, coal, ice, etc., have at least four-inch tires.

Syracuse, N. Y.

FROM THE CHAMPION WAGON COMPANY.

WE find it a very difficult matter to answer your favor of recent date, in regard to width of tires. While we may have an opinion, yet it is based entirely on theory and may be very wide of the mark, and there is such a diversity of opinion among our customers, that it is a difficult matter to draw conclusions from our experience with the trade. The average width of tire for a lumber wagon is one and one-half inch. Our price for wagons is based on tire of this width. For tires wider than this, we charge at the rate of $5 00 per inch, for all in excess of one and one-half inch for four wheels. Our experience has been that most farmers use wide tires, because they do not cut up their meadows as badly as narrow tires. In many localities, users of wagons are forced to use broad tires by the street commissioners, who will not allow heavy loads with narrow tires to be used on the highways. On good roads, the narrow-tired wagon is of lighter draught, as the wheels are not so heavy, and on muddy roads the draught is also in favor of the narrow tire, for the reason that the mud will pile up in front of the wide tires, while the narrow tires will cut through it. On meadow land, there is no question but that the wide tire has the lighter draft for reasons that are palpable.

Owego, N. Y.

FROM THE WEBER WAGON CO.

The difference in cost between the narrow and broad tires on a three or 3½-inch cast skein farm wagon, would be about $5.00. The advantages claimed for broad tires are that they will not sink into the ground as deeply as the narrow tires where it is soft or marshy; then, when running over meadows, they will not cut up the soil as much as the narrow-tired wagons. The draft on soft or marshy ground is much lighter than with the narrow tire for the reason that it will not sink into the ground as deeply as the latter. The broad-tired wagon is the better of the two for either sandy or muddy roads. The only objection to it on black ground, is that most of the wagons which are used have narrow-tires and the ruts being correspondingly narrow, the broad tires are apt to wedge and draw heavier. If the broad tires were used generally, there is no question but what the roads would be better and the ruts not so deep.

Chicago, Ill.

FROM B. A. GARLINGER.

Our customers prefer wide tires, because they are charged only one-half toll on our turnpikes. An additional advantage in favor of wide tires in hauling through the fields is that wide tires will not cut up the ground as much as narrow tires. I know of but one place where they would fail, and that would be on a mud road in very wet weather; there the narrow tires would have a slight advantage. I do not think it would pay here to have two sets of wheels.

Hagerstown, Md.

FROM W. H. WILCOX.

For farmers wide tires are especially preferable, because they do not cut up the meadows like narrow tires; on soft or muddy ground or roads, a load draws easier as it does not cut down so deeply. They are preferable under all circumstances, except on hard, stony roads. I do not think it would pay a farmer to have two sets of wheels. Farmers are using wide-tired wagons very extensively in this section now, and I think it will be only a few years before the narrow tire will go out of use almost entirely.

St. Charles, Ill.

FROM J. B. RUNKLES.

Here are several reasons why we prefer the wide-tired wagons: Half toll on our pikes; they will not turn over on hillsides so easily as the narrow-tired; they will not plow up the ground so deeply. We do not want the narrow-tired wagon at any price.

WATER PIPES FOR 40 RODS.

E. D. G., Ashburnham, Mass.—I wish to bring water to my dwelling through a half-inch lead pipe from a distance of 40 rods, during which there is a fall of 18 feet. Is there any other kind of pipe equally good, but costing less? How deep in the ground should the pipe be laid, if the water run constantly in cold weather? Will water running through a half-inch pipe in frozen ground freeze if the stream is only one-eighth of an inch in diameter? Will pretty sharp angles in the pipe greatly affect the velocity of the flow? Is there any way of testing the purity of the water?

ANSWERED BY HENRY STEWART.

Lead pipe is objectionable for the conveyance of water, because of the injurious effect of the water upon the metal. All water contains more or less carbonic acid, and this acid acts on the lead all the more strongly as the purity of the water is greater. When the water contains lime—that is, when it is "hard" water—in time a coating of the lime is deposited in the pipe and protects the lead from this action. The rustless iron pipe, the inner and outer surfaces of which are changed by a chemical process into insoluble magnetic oxide of iron, is the only really safe pipe to use for conveying water for domestic use or for animals. This pipe, however, is rigid, and cannot be bent so easily as lead pipe, but it may be curved to a considerable extent when desired, or angle unions may be used to change the course to a right angle or less, as the case may be; 600 feet of this pipe or nearly 40 rods in length have been laid by the writer in a semi-circle around a hill without using these angular unions, the pipes bending sufficiently for the purpose. The cost is much less than that of lead pipe, and being free from rust, it is indestructible. A half-inch pipe is too small to carry water 40 rods, as the flow is so much retarded by friction and adhesion of the water. If the pipe be protected by a covering of straw a few inches deep before the trench is filled in, there will be no danger of freezing although the ground may be frozen around the pipe, if it be laid two to three feet deep. The greatest trouble in a pipe laid nearer the surface is in the hot weather, when the ground being warmed expands the free air in the pipe—the pipe always contains more or less air as the water will not fill it because the flow is always retarded more or less in all small pipes—and this expansion of air at any vertical bend of the pipe, which cannot be avoided without very accurate laying or an exact plane, will reduce the flow or stop it unless the flow is occasionally re-enforced by forcing in water under pressure to drive out the air. This accumulation of air in pipes gives a great deal of trouble, the cause of which is not suspected, when the pipes are subjected to an increased temperature in the summer by being laid near the surface. A high head, of course, by affording more pressure and a larger flow will prevent this, if the vertical bends are not much more than the diameter of the pipe. Sharp turns have a considerably retarding effect upon the flow and would be sufficient to stop it in a half-inch pipe 600 feet long. A chemical analysis is required to test the purity of water, especially for the presence of lead in it. The solubility of lead is so great, when exposed to the action of a current of spring water, as to render it certain that the water would be made unsafe in a short time. I would suggest that a one-inch rustless iron pipe should be used, and laid as evenly as possible in a carefully graded trench not less than two feet deep with a covering of leaves, straw, sawdust or of narrow boards, so as to leave an air space around the pipe. There will then be no difficulty in the conveyance of the water, and no injurious effect or even any taste of the iron. The pipe is frequently mentioned in the business columns.

GRAPES ON LIGHT BLACK DRIFT SOILS; A STRAWBERRY BED; RHUBARB WINE.

P. T. N., Weston, Neb.—1. My 80-acre farm of creek-bottom land has two feet of black soil underlaid with 50 feet of yellow clay. It produces good crops of corn and small grains, but grape-vines set out two years ago have made only a poor growth. Would it be well to use gravel on the land? The ground has been made rich with manure. 2. How shall I prepare land for strawberries to be set out next spring? 3. How can I make wine out of rhubarb?

ANSWERED BY PROF. J. L. BUDD.

1. On the black drift soils east of the Missouri divide there are patches of black, muck bottom land on which it is difficult to grow the grape or any other garden fruit. But even the bottom lands of the Missouri Valley and the creek valleys of Kansas and Nebraska have enough potash and other essentials of healthy plant growth. From past observation I suspect the main trouble with these vines comes from *too shallow planting*. To illustrate: A large farmer on the Missouri bottom assured me that he had planted Concord vines repeatedly, but that they had dwindled away, and that he did not believe the vine could be profitably grown on such soil. I requested him to try once more by planting the vines 18 *inches deep*, filling in the soil gradually as they made growth. In the Spring of 1884, he put out 100 vines in this way, and he is now proud of his little vineyard. If planted shallow on such light porous soil, the roots are injured by the deep freezing during their first stages of growth. But on such soil, it is not best to apply stable manure, at least not while the vines are young. 2. The ground should be plowed in the fall, the action of frost during the winter pulverizes and mellows the soil, and lessens the danger of the plants being destroyed by cut-worms. On such soil, no manure is needed. 3. The juice from the rhubarb stems is managed in a small way precisely as we manage the juice of the grape, currant, gooseberry, etc., for home-made wines. The best variety for this use is the Linnæus, but at best it is a poor substitute for well-made wine from the grape or from about any one of our garden fruits.

CRYSTALLIZED AND GLACED FRUITS.

Several Subscribers.—What is the process employed by California packers in preserving fruits, etc.?

ANS.—The process employed in preserving fruits in a crystallized or glaced form is a French process, having been employed in that country for many years. The theory is to extract the juice from the fruit and replace it with sugar sirup, which hardens and preserves the fruit in its natural shape. The fruit should all be of one size and of a uniform degree of ripeness, such as is best for canning. Peaches, pears, and similar fruits are pared and cut in halves; plums, cherries, etc., are pitted. After being properly prepared, the fruit is put in a basket or bucket with a perforated bottom, and immersed in boiling water to dilute and extract the juice. This is the most important part of the process, and requires great skill. If the fruit be left too long, it is over-cooked and becomes soft; if not long enough the juice is not sufficiently extracted, and this prevents perfect absorption of the sugar. After the fruit cools, it may again be assorted as to softness. The sirup is made of white sugar and water. The softer the fruit, the heavier the sirup required. The fruit is placed in earthen pans, covered with sirup, and left about a week. This is a critical stage, as fermentation will soon take place, and when this has reached a certain stage the fruit and sirup are heated to the boiling-point, which checks the fermentation. This is repeated, as often as may be necessary, for about six weeks. The fruit is then taken out of the sirup, washed in clean water and either glaced or crystallized, as desired. It is dipped in thick sugar sirup, and hardened quickly in the open air for glacing, or left to harden slowly if to be crystallized. The fruit is now ready for packing, and is said to keep in any climate. The business should not be attempted by inexperienced persons except on a small scale.

COLORING BUTTER.

T. M., Randolph, Dak.—In coloring butter for shipment where there are several churnings in the tub, how can butter color be used so that the butter will be all quite uniform in shade?

ANSWERED BY E. L. BASS, SECRETARY VERMONT DAIRYMEN'S ASSOCIATION.

I do not approve of packing more than one churning in a tub. The packages should be adapted to the size of the dairy so that one or more may be filled at each churning. Much

care and good judgment should be used in coloring, first to secure the exact shade desired, and then to keep it uniform throughout the season, but not throughout the year. Do not try to make June butter in December. To do this the changes which are taking place in the dairy and the changes in feed also must be kept in mind, while a given quantity of butter color of known strength is being applied to a given quantity of cream. In short, use common sense.

ODOR FROM THE MANUFACTURE OF SUPERPHOSPHATE.

C. A. M., Cortland, N. Y.—Is the manufacture of superphosphate for fertilizer, as at present conducted, offensive to the sense of smell?

ANS.—There *need be* nothing offensive in the manufacture of superphosphate. But in general, the bones used, and the acid, are somewhat too odoriferous for very close acquaintanceship. Frequently the "sludge acid," a refuse of the petroleum refineries, is used instead of the fresh acid; this waste acid being cheap, but it has a disagreeable odor. When the fertilizer is made of rock phosphate and pure acid there is nothing disagreeable about it. If the manufactory were 40 rods only from a dwelling there would be at times, when the wind favored it, a disagreeable odor that would be annoying to some persons, but in no way injurious to health.

Miscellaneous.

Y. A. S., College Springs, Iowa.—The plant sent is Daucus carota—Wild Carrot. It is a vile weed, biennial, and spreads with great rapidity. Thorough cultivation is the only way to subdue it.

J. H. S., Amite City, Iowa.—Grass No. 1 is Paspalum virgatum. We do not know of its cultivation. It is, however, relished by grass-eating animals, and if cut and dried before the seeds harden it is said to make a nutritious hay. No. 2 is Tripsacum dactyloides—Sesame Grass. Of little value as food.

A. P. S., Belford, Mass.—What is the best remedy for the asparagus pest, samples of which are inclosed?

ANS.—In the box sent we find the eggs, larvæ and perfect insects of the asparagus beetle. Paris-green or London-purple will probably prove efficacious.

M. P. C., Capoosa Works, Pa.—Where can I buy the pamphlet, "Food Products," by Thos. Taylor, containing descriptions, etc., of 12 edible mushrooms. It was "noticed" in a late RURAL?

ANS.—Send stamp to Dr. Thomas Taylor, Department of Agriculture, Washington, D. C.

D. A. Y., Riverhead, L. I.—My potatoes on my Contest Plot, were struck with the blight about three weeks ago, and now the leaves are dead; but the stalks are still green. Is it permissible to dig them now, or shall I wait until the stalks are dead? They are rotting somewhat.

ANS.—They can be dug at any time.

L. S., Prescott, W. T.—What is the best and cheapest fence for keeping rabbits out of an orchard?

ANS.—Any fence, in the R. N.-Y.'s estimation, that would keep out rabbits would cost too much. The best suggestion we can offer is to use wire netting about the trees. This can be done at a small cost, and will prove an effectual defence.

I. F., Danville, Ill.—What is the best way to winter grape-vines? Some say: Bury them in the ground, and cover them lightly.

ANS.—For your climate (middle Illinois) we should prefer merely to lay the canes down, holding them by stones, blocks, sods or something of the kind, and then cover them lightly with leaves, evergreen boughs or coarse litter of any kind.

DISCUSSION.

THE ROT OF POTATOES.

DR. HENRY STEWART, MACON COUNTY, N. C.—The "rot" of potatoes, so-called, has always been a matter of disquiet in regard to the possible injury that might occur from the consumption of the diseased tubers as food. I well remember the first remarkable origin of this question, and its great and special importance at the time. It was in 1847-8, when this disease ruined the staple food of the Irish people and caused a famine so disastrous as to have become one of the standing finger-posts of history. It was followed by an epidemic which destroyed a vast number of its victims, and which, with the actual starvation, mostly helped to reduce the population of the unhappy island from eight millions to less than five. The question then arose, was this disease—then called the Irish fever—a result of the consumption of the diseased tubers. This subject was discussed in medical circles and became very interesting to the physicians and medical students who volunteered in large numbers to assist in the crowded hospitals hastily erected for the accommodation of the victims of the epidemic. I was one of the students in the largest hospitals in London, who thus volunteered, and spent several weeks in the west of Ireland, where the epidemic was the most virulent. I mention the circumstances because I believe it was the first time that the question arose and I know of no special injury of the kind occurring since, although several practical tests have been made in feeding the diseased tubers to swine and other animals.

The diseased tubers were cooked and eaten by the physicians, and a good deal of other investigation was made, all of which resulted in a unanimous opinion that the fever which prevailed was the effect of the low condition of vitality among the half-starved, and in many cases completely starved people, whose food was either wholly destroyed or rendered innutritious by the disorganization of the starch tissues of the tubers, by the so-called disease, the character of which was then unknown. Scarcely a sound potato could be found and the blackened tubers, only partly escaped, were commonly eaten, not only in Ireland but also in England and Scotland, out of dire necessity, and yet, excepting among the impoverished Irish, there was no outbreak of disease. The cooking of the potatoes wholly destroys whatever might have been injurious, or might have been supposed to be so, and the effect of the disease in the tubers was simply the partial destruction of their nutritious substance. So far as I have since been able to learn through occasional reports on the same subject, in various publications made from time to time, and from my own experience in feeding diseased potatoes, I have never had any reason to doubt the accuracy of the belief resulting from the very careful study of the question under the circumstances mentioned.

Since then the rot of potatoes has been a subject of scientific study by the most skillful investigators, chiefly by Professor Smith of England, and (especially so) by Prof. De Bary of the University of Strasbourg, who discovered the manner of the hibernation of the fungus and the character and life history of the resting spores, and who set at rest all doubts and conflicting opinions about the biology and peculiar nature of the disease. The result of De Bary's investigations were published in the Report of the Royal Agricultural Society in 1875, and, so far as I know, nothing has been added to what was then made known. The blackening of the tubers is due to the growth of the spores, or fruit and seed, of the fungus, just as the black mass of smut appears in the ears of corn, or of wheat; and while these spores may be, and undoubtedly are, when eaten in large quantities, poisonous and productive of disease in animals, producing gangrene of the extremities, as was the case in Kansas two or three years ago, yet cooking completely disorganizes them and destroys their vitality and power of injury. Consequently diseased potatoes may be eaten with impunity by persons when they are cooked, and when fed to animals in the same condition, are wholly innocuous, the nutritive quality only being deteriorated to the extent of the destruction of the starch and cellular tissues of the tubers.

Possibly some lingering doubt may remain in the minds of some persons through the supposed analogous case of the poisonous mushrooms, whose virulent character is not destroyed by cooking; but there is no analogy between the two cases. The poison of the inedible mushrooms is inherent in their substance, and consists of a peculiar alkaloid of a similar character to that of the wild parsnip, so-called, or cow-bane, (Archemora rigida) or the poison hemlock (Conium maculatum) and is not destroyed by cooking, while the organism of the smut or potato fungus (Phytopthora infestans) is wholly destroyed and rendered harmless. Indeed thousands of animals eat smutty corn and fodder with impunity, and pigs will eat raw diseased potatoes without harm, as I have found by several tests. Quite possibly any harm that might occur to animals through the eating of the rotten potatoes may be due to disturbance of the digestive organs rather than to actual poisoning, and in consequence of the excessive quantity of innutritious matter; just as fatal diseases of animals are caused by similar results from the excessive use even of food that in moderate quantities would have been healthful. Therefore I think all doubt whatever may be discharged from the minds of persons interested in the question.

But the term "germs of rot" is used in this question, and this term calls for some remark. The germs are the resting spores of the fungus and these only; and these are the brownish-black substance which discolors the tubers, before the diseased parts decay and form the fetid pulp which is the result of the rot. The substance of the tuber may dry up and become dead, and yet contain the germs of the "rot." A potato that is not discolored and is free from the usual decayed spots is quite free from the disease, although when stored in pits or in a cellar, the sound potatoes may become infected by contact with diseased ones. The germs are apparent in the tubers and where these are free from dark spots or patches they are healthy and consequently healthful. A word may be spared here for the remark that if the diseased potatoes are separated from the sound ones and these are kept in a dry place and sprinkled with air-slaked lime, any germs of the rot that may adhere to them will be destroyed by the lime and all infection prevented. This easy method will secure from injury potatoes not already diseased, and will stop the progress of the disease unless the decay has made considerable progress, so that no apprehension need be felt in regard to the germs of the rot in this way.

The second question lately asked in the RURAL is partly answered above, and may be more fully answered by the statement that so far no special injury or disease to persons has been known to occur. If any injury should result from the use of diseased potatoes it would most probably appear in diarrhœa or cutaneous eruptions, as sore mouth and gangrene of the extremities, in animals to which the raw diseased potatoes may be fed. The life of the germs or resting spores continues at least for a year, but how much longer is not known. It is probable that the germs may remain in the soil many years, being of an oily character and resistant to decay, like the smut spores. The fact that potatoes are grown for several years without any appearance of the disease and may then be affected in a wet, warm season, which is favorable to the germination of the spores, indicates that the spores may remain in a dormant condition for several or many years and then germinate when the favorable moisture and warmth occur.

The danger to public health through the distribution and use of diseased potatoes is scarcely worth attention. No disease that has been attributed to it has been experienced since the Irish epidemic referred to. As no one eats raw potatoes, and cooked ones are entirely safe, it is simply a question of domestic economy in regard to the waste resulting from the decay, and this is settled by the aversion of consumers to purchase damaged tubers. The loss will be to the growers who may reduce this to a minimum by digging the potatoes as soon as may be, carefully sorting out the sound ones, drying them thoroughly, and storing them in airy bins or barrels ventilated by means of holes in the sides, and dusting them with air-slaked lime. The unsound ones should be dried, dusted with lime and kept on a floor in an airy shed and used, cooked, for feeding to pigs, for which they are worth as much as sound ones, less the waste of destroyed tissue which is very small in those potatoes which are not badly diseased. Cooked potatoes are worth twice as much as raw ones for feeding, and will return 25 cents per bushel to the feeder, in the pork. I might say, in conclusion, that my crop is rotted to a small extent and that I am digging them and treating them as above mentioned, storing them in a dry shed on a board floor raised from the ground, liming them, and covering with straw the heaps, made quite shallow so as to air them freely. I expect to have no further loss. I am feeding the badly rotted ones to pigs and the others to cows, uncooked to test the questions here raised. The only rot in my crop is in a piece of highly-manured wet land.

COST OF FARM LIVING.

H. V., CRANFORD, N. J.—The article by J. N. Muncey, on page 508, in relation to cost of living on a farm, buying groceries, etc., treats of a subject of great importance to farmers. I am under the impression, from my observation, that very few farmers keep accurate accounts, or know what their supplies cost them for any given period. Did they do this, and give the farm credit for the cash value of what they consume from it, they might find that the farm paid better than they think. Farmers do not realize the value of these things that seem to come to them so freely, as do those who pay cash for them. There is no earthly reason why farmers should not combine for the purchase of needed supplies. On the contrary, there is every reason why they should. Combination is the power which is stirring the manufacturing, mercantile and financial world to its foundations. The class which does not combine will get left. As Mr. M. suggests, the dealers will object to this. One of them has had the brazen effrontery to do so in the RURAL. I used to be an advocate of home-trade, patronizing home merchants, and keeping the money in the home town. I was in the small-fruit business. I had strawberries to sell; the grocer would pay me just what he could buy strawberries for in the city. To be sure the latter were picked green, were shipped hundreds of miles, and were very poor specimens. Then he was mad, because I proposed to sell them direct to customers, and get what they were worth. This experience repeated a few times cured me of the notion that I must spend my money at home to "build up the town." Then when the Grange to which I belonged, sent to the city, and bought a large quantity of supplies at wholesale prices (which many of the members would not have done if the dealers had not been charging from 50 to 150 per cent. profit), some of the dealers were furious; and one of them raved and swore like a madman. Haven't the farmers the same right to combine as other people? Apparently not. There are many things that can be bought to advantage by a combination of farmers, and then divided, which it would not be feasible for one farmer to undertake to purchase. The Grange has been a great educator in this direction, and if all farmers were united in this way, instead of a minority of them, there would be a strife among dealers to secure their trade. Before the Grange agitation, a man could not buy goods at wholesale rates, unless he were a dealer; now any man with the cash can do so. There is a difference of opinion as to the advisability of buying sugar by the barrel. The margin between the wholesale and retail prices is slight. Many claim that with a large quantity on hand, it will be used more freely than necessary, and that any possible saving will thus be offset. An immense saving can be made on coal, but there were formerly many railroads which would not ship a carload of coal for any one but the regular dealers. The inter-State Commission may settle this. Kerosene oil is a very disagreeable thing to be bringing from the store in a can, slopping all over the wagon, robes, blankets, clothes, etc., which is quite a strong argument in favor of buying it by the barrel. Some think that tea and coffee will lose their strength if any great quantity be purchased at once; but they will not lose their strength any faster under the good housewives' care than they will in the average country store, besides being kept a great deal cleaner. If the farmer does not feel like buying his goods at wholesale, he can often make quite a saving by buying in larger quantities of the home grocer. My grocer charges 16 cents per gallon for the best oil. He will sell five gallons for 14 cents per gallon. Soap, lamp chimneys, etc., may be bought for quite a discount by the dozen. These may seem like small matters, but I think the secret of so many farmers' failures is their carelessness in small matters. But the greatest saving on the farm can be made in the purchase of implements, machinery, etc. There are immense profits made on many of these. I am glad this subject has been started, and I hope to see it thoroughly discussed.

CHINCH BUG DISEASES.

J. R. H., WELLSVILLE, KANSAS.—The seventeen-year locust must be a very healthy insect until after it has sung its song and deposited its eggs, then "some contagious disease appears to carry the pests off by the million." Our common grasshopper and its cousin the grasshopper of the West are very healthy insects until in the fall after they have deposited their eggs; then "some contagious disease appears to carry them off by the million." The chinch bugs—aye there is the rub—the chinch bugs are exceedingly healthy insects until late in the spring after they have deposited their eggs then "some contagious disease appears to carry them off by the million," then if it should remain warm and dry the young bugs will hatch out and be the healthiest little creatures you ever saw; but should the weather be cool and wet, they will be attacked by some contagious disease like that which attacks young chickens after they have been out in a cool, hard rain.

Last spring "the oldest inhabitant" remarked that he had never seen more chinch bugs come through the winter than he did last. They swarmed in the wheat and oat fields to deposit their eggs, which they laid "by the million." This has been a very wet season, there being hard rains every few days all through the spring. I watched the chinch bugs closely in the oat field. After a hard rain I could see great numbers of very young bugs and eggs washed from the oats into the depressions. In that condition the young bugs died and the eggs did not hatch. I suppose the wise ones would say they died of some contagious disease. I am out of

patience with this disease theory. It is a humbug pure and simple. The old bugs die a natural death; the young bugs are killed by the wet.

REMEDY FOR A KICKING COW.

J. B. K., PORTLAND, OREGON.—The article on page 459 of the RURAL, entitled the "Kicking Cow," and the title-page illustrations of that terror of the milking yard remind me that I have a remedy for treating the vicious brute. I have used it for a dozen years with perfect success. I have never seen it in print. It is very simple, easy of application, does no injury whatever to the animal and is perfectly effective. I have never known a failure: Take a small rope or cord about the size of a clothes-line; make a loop in one end; hold the loop end in one hand; drop the other end over the cow's back; pick it up and pass it through the loop; then slip it back just behind the hips, bringing it underneath just forward of and close to the udder, adjusting it so that the loop is near the back-bone. Now draw the rope through the loop tightly and fasten it, the more tightly the better if the animal is very vicious. On the first application, she will jump and try to kick and perhaps bellow; but let her kick, she will soon get tired of doing so. Now you can sit down and milk without the least danger. You can hardly provoke her to kick. If she should still try to kick, tighten the rope and continue to do this till she gives it up. Three applications in succession will cure the worst case I ever saw. Treat her kindly and gently all the time without the least excitement.

BLUEBERRIES.

P. C., MILFORD, N. H.—Where there are no blueberries perhaps it may pay to try to cultivate them; but I know of one bush set out over 20 years ago that never had a crop until this year. It has not been cultivated for years, but it is in a cultivated field. This year there were between six and eight quarts on it. Here the blueberry is abundant and the women and children get the most of their money picking berries. The price this season runs from 14 cents per quart down to five cents. Where people do not own pastures they pick and take two-thirds; the owner has one-third. Our family of four—three children and their mother; two of the children less than 10 years of age—picked over $50 worth this season, and on account of the rains there are hundreds of bushels not picked. I saw 27 bushels put on the train on August 3d and some days from 100 to 150 bushels are shipped on the different trains. We are 54 miles from Boston and there is no transfer. The expressage is 25 cents per bushel on an average. Crates are returned. The best way here to cultivate them is every two or three years to mow and burn the vines. The berries will then be larger and it will be easier to get around to pick them.

CATTLE ON A VERMONT FARM.

E. A. F., HANCOCK, VT.—My farm comprises about 300 acres. It is the same on which my father settled in 1806—when this section was an entire wilderness. It is mostly cleared land now. The wood-land is mostly spruce and maple. I have one of the finest mountain pastures in the State. My cash crop is pasture. I have summered 105 head of stock this season; not so many as usual though feed is very good. The average number of stock I winter is eight cows, a team, 30 sheep and a few head of young stock.

What Others Say

PITHS AND SUGGESTIONS.

TAKE a Cooley can or any other can in general use in creameries, says George Parr in the Farmers' Review, fill one with warm milk just drawn from the cow with the animal heat in it, submerge it in ice-cold water, and fill another can and allow the animal heat to escape, say 30 minutes before submerging it, let both cans stand for 24 hours. On the majority of the cans that he has seen in general use, the lids are not constructed to be submerged, but this makes no difference. Cover one tightly, so that there is no ventilation, and allow the other can to remain uncovered until the milk becomes cold before putting the cover on and let them stand in ice-cold water up to the rim for 24 hours. When the cream is removed, if there is not a disagreeable taste and smell to the cream taken from the can that was not ventilated, then the professors and hundreds of others are wrong, and Mr. Hiram Smith is right in his assertion that aeration before submersion is not necessary.....

THE short potato crop in the East will be more than counterbalanced by the unusually large yield in the West.....

JOHN GOULD says, in the Weekly Press, that a cow will consume easily 100 pounds of the best lawn mowings in 24 hours and maintain her flow of milk. Dry these 100 pounds of clippings into hay and it weighs from 12 to 14 pounds. Put the same cow upon this dry food, the same in original amount that she found to her satisfaction. How long will the same cow thrive and give full pails of milk on 12 pounds of dry hay? Give her 24 pounds of this hay and she will do better, and yet more satisfactorily upon 36 pounds, the product of three days' rations in its succulent stage. Now, can we afford to feed in the winter on hay that at least represents twice the food needed when this hay was grass?.....

KEEP it in mind, readers. "The labor on the part of the farmer is *increased* as the grade of the fertilizer purchased and used *decreases*".....

THE RURAL NEW-YORKER is bitterly disappointed at the results of its potato experiments this season—but discouraged? No. We did our best, and there is a satisfaction in that.....

THE results of the Women's Potato Contest will unquestionably prove interesting, suggestive and instructive.....

AS TO harvesting and haying machinery, it seems to Pres. W. I. Chamberlain, as he expresses it in the Ohio Farmer, that no farm that has much grain and much heavy clover, Timothy and Hungarian, can afford to be without the best makes of the following implements: twine-binder, mower, hay-tedder, horse-rake and hay-loader, or rather pitcher. His team of 1,200-pound horses handles a twine binder with ease, poking along and kicking flies as if the draft were no consideration. The ground was level, tile-drained and firm. If soft or hilly, the draft would be heavier. It is a delight to sit on the high seat and simply drive and hear the machine click, click, click, as it kicks off the compact bundles, saving all the wheat. It cuts an acre an hour with a rather slow-walking team. It goes in at his barn doors for storage without folding, and takes up not much room with the tongue taken off. The back-aching labor of cradling, raking and binding has forever gone.....

THE REV. T. DE WITT TALMAGE says a great many good things, but he also says some very foolish ones. In a recent sermon he tragically declared that "the Almighty will smite this people if they do not stop inventing machinery to take work from poor people," and he hoped that not another tool would be invented for 500 years! Mr. Talmage is like the cow that gives a three-gallon pail of milk and then kicks it over. The Ohio Farmer advises him to go to China, where they employ no machinery at all, but do everything by hand. The Flowery Kingdom would just suit him. They allow no modern innovations there. Even horses are rarely seen, and men and women are the beasts of burden as well as hewers of wood and drawers of water.....

MR. M. J. LAWRENCE, of the Ohio Farmer, when a young man, was sent to Japan and China by one of the leading sewing machine companies, to introduce its machine. He selected the largest tailoring establishment at Hong Kong, set up the machine, operated it, and explained its advantages through an interpreter. He tried particularly to impress the fact upon the mind of the almond-eyed proprietor that with this machine one man would do as much work as nine men could do by hand. "Yes," the proprietor readily admitted, "but what would the other eight men do?" That was his knock-down argument. He would not buy a machine, and none of them could be sold in the kingdom, But unfortunately for Mr. Talmage's theory, the Chinese people are among the poorest and most wretched on earth The absence of all modern machinery does not make them richer or happier. The multiplication of machinery and devices for lessening labor and decreasing cost of production is an absolute blessing to laboring men.....

"THE RURAL NEW-YORKER recently quoted from the Massachusetts Ploughman an article on bunching asparagus, by W. J. Green, of the Ohio Experiment Station. That article was written expressly for the Ohio Farmer, and if the Ploughman published it without credit the RURAL is not to blame. The Farmer always gives due credit, and insists upon being treated likewise. The official statements of the experiment stations are always published as such, and credit is given to the various bulletins issued. These are public property of course. But the articles over the signatures of the experimenters are paid for; they are our property, and if used by contemporaries they ought to acknowledge the source."

The above is taken from the Ohio Farmer. It was credited to the Ploughman because it appeared in that journal as if written expressly for it. The R. N.-Y. has never knowingly copied an article without giving due credit to the publication quoted from. Our position is that any editor that will appropriate such matter will appropriate anything else, if he can do it with safety. In other words, an editor that will print without credit original articles written for other periodicals is simply a thief, and the editor knows it too. The only pity is that his readers for the most part are kept in ignorance of the fact...

PROF. B. D. HALSTED finds that the common asparagus is heliotropic, *i. e.* follows the sun in its daily course. In early morning the shoots are nearly upright, but when the sun is two hours above the horizon the same stems lean unmistakably to the eastward. At noon the stems are leaning somewhat to the southward and at evening they point westward. The curving is most prominent with average-sized stems which have escaped the gardener's knife, and are between one and two feet in hight....

Horsford's Acid Phosphate,
For the Tired Brain
from over-exertion. Try it.—*Adv.*

ABSTRACTS.

——C. L. ALLEN in the American Garden: "The finest show of flowers I have ever seen in the garden resulted from sowing a paper of single dahlia seeds in a hot-bed in April, transferring the plants to the border in June. During August, and until frost, the plants were a mass of bloom, all colors, from the purest white to the darkest maroon, pure yellow, with some striped and variegated forms of surpassing loveliness; about fifty plants in all, not one poor one, the whole costing 25 cents."

——J. C. VAUGHAN in American Garden: "Rose, Madam Jamain (American Beauty). Why in the name of honest dealing should not the name American Beauty be dropped forever, instead of perpetuating the disgrace which certain florists of this country brought upon us by introducing this old sort under a new name."

——MIRROR AND FARMER: "The possibility of cows pouring out such abundant quantities of rich milk as our best herds are now capable of has only lately come to be recognized. Truly, through human art, the cow is a transformed and to a large extent a man-made creature in this matter of milk production.

Being so far an artificial production, it is only by art that the improved milch cow can be perpetuated. Therefore the high-class dairy cow pre-supposes and is based upon specialized skill in her human keepers. Dairying is an art requiring great intelligence and much acquired knowledge.

——HUSBANDMAN: "A farmer is a capitalist and laborer, and therefore wants labor and capital both justly treated in the administration of laws."

——FARMERS' REVIEW: "If Chicago wins the World's Fair of 1892, let arrangements be made for the holding of a national (or international) live stock exhibition which shall throw in the shade anything of like nature ever held in other countries."

——POPULAR SCIENCE NEWS: "A curious experiment in osmosis.—Take two eggs of equal size. Carefully dissolve the shell of one with dilute hydrochloric acid, and immerse it in pure water. In the course of a day or two enough water will pass through the outside membrane to cause it to nearly double its volume, as may be shown by comparison with the second egg, which is used as a standard."

——"NOTWITHSTANDING the wails of the pessimists, mankind are steadily improving in bodily strength and vigor. Even the immense consumption of patent medicines fails to stop the improvement—a fact which goes to prove the general absence of any medicinal qualities whatever in these preparations."

——NEW ENGLAND FARMER: "'I believe that a young man with business ability, industry and a capital of two thousand dollars will be much surer of success in any one of several branches of farming, if he has a liking for the business, than in a venture in any other business.' This is the opinion of Hon. W. R Sessions, Secretary of the Massachusetts Board of Agriculture, a man who is a practical farmer, who has had a wide experience and who has excellent judgment. Such testimony is very valuable."

THINGS NOT TO BE SORRY FOR.

——N. Y. HERALD: "You will not be sorry for hearing before judging;
For thinking before speaking;
For holding an angry tongue;
For closing the ear to a talebearer;
For disbelieving ill reports;
For being kind to the distressed;
For being patient toward everything;
For doing good toward all men;
For asking pardon for all wrong;
For being courteous to all."

——PHILADELPHIA WEEKLY PRESS: "When the weather is wet, as it has been this summer, tomatoes make too much branch and too little fruit. To get the latter, run a spade in the ground about them to cut the roots. The check advances the fruiting."

——"The purely-bred horse of the desert has good feet and legs, good heart and lungs, courage and docility. Such qualities are not bad for grafting on any stock."

——VERMONT WATCHMAN: "Is it not plain that the American farmer, and especially the New England farmer, needs to be a good deal of a man? He *is* a good deal of a man. When we see how comfortably many of them manage to live, and how much "ahead of the world" a fair proportion of them are able to get, there cannot be any doubt that the high personal qualities of hundreds of our New England farmers place them well up in the scale of absolute manhood. If the farming occupation is despised in the cities, it must be only by those who do not realize what it is in these days to be a successful farmer."

——"BUT THERE ARE TOO FEW of whom this can be said, and too many among us are laboring under discouragements that kill out spirit and energy. They are doing a business which they do not sufficiently well understand to make it profitable. These are like the small store-keepers and manufacturers in the cities. The world seems to have got tired of them. There is no longer place for mediocrity in business—even the business of farming. This is what many think and hundreds say."

——ORCHARD AND GARDEN: "We believe with the R. N. Y. that bananas and pine-apples possess such distinctive flavors and qualities from other fruit that a person who wants one will not take the other in its place."

THE
RURAL NEW-YORKER.
A National Journal for Country and Suburban Homes.

Conducted by
ELBERT S. CARMAN.

Address
THE RURAL NEW-YORKER,
No. 34 PARK ROW, New York.

SATURDAY, AUGUST 31, 1889

As the Report of the Special Commission on Diseases of Swine would take up two columns, and as we cannot see that it would be either instructive or interesting to our readers, it is omitted. The R. N.-Y.'s columns are somewhat too valuable to be given up to absolutely worthless reports.

HERE is an idea, friends. It comes from a Maine subscriber:

"If any of the RURAL'S subscribers wish a perfect corn-cutter, let them cut away the handle of a hoe so as to leave about 18 inches of it, and they will have the best implement known. I ridiculed this idea; but one blow with it completely converted me. It is play to cut corn with it, and the work can be done very rapidly."

GRAPES are smaller than ever before at this time in the season, though the bunches average as large as usual. The vines have made an unusually strong growth, which may account for the smallness of the berries. Moore's Early, Colerain, Early Victor and Cottage are the first to ripen. Many varieties are rotting. The Eaton bears the largest berries which, as well as the vine, are free from rot and mildew. It is a showy, very desirable grape. The Colerain again shows itself worthy of all the R. N.-Y. has said in its favor.

FARMERS are sometimes urged to buy "sore" mares that have worked hard before trucks or horse-cars, and to use them for breeding purposes. This seems all right in theory; but of late the R. N.-Y. has received complaints to the effect that many of these mares fail to breed. Whether it is the rough treatment to which they have been subjected in the city, or whether it is over-feeding on grain that caused the trouble we cannot say. We would like to have those who have tried these city mares for breeders, tell us what they have found them capable of.

"I know that I am advocating the unpopular side of this question, but have had the best evidence before me for years that my practice of pasturing meadows does them no injury, and is of great benefit to the dairy." —C. E. RICE, page 574.

THE R. N. Y. wants to have a little hand in making suggestions as to the National Flower as well as its contemporaries. It proposes first, the Moccason Flower (Cypripedium) or Lady's Slipper; and, second, the Cardinal Flower (Lobelia). Of the first, we have C. arietinum, parviflorum, acaule, spectabile, pubescens and candidum, all natives of our own country, some of which are among its most striking and oddly-beautiful flowers. Of the second we have, among a dozen species, the everywhere popular Cardinal Flower, Lobelia cardinalis, found in the moist grounds of nearly every State in the Union.

NEWS comes from the Northwest that the Northern Dakota and Northern Pacific elevator companies have effected a business deal whereby the competition for the grain of North Dakota will be discontinued, and farmers will have to accept such rates as the elevator companies may choose to offer. What is the moral difference between the conduct of such a combination of plunderers and that of a band of highway robbers? Of course, there's a vast legal difference. The successful robber detected among respectable men, is disgraced and punished; whereas the successful plunderer, though known to all men, is respected and petted. There are many crimes—black ones, too—not yet included in the statute laws.

THE horse and mule markets in this city open very satisfactorily this season. This is one of the best markets in the world for fine horses. Buyers are constantly on the outlook for fast driving horses, matched pairs and stylish coachers, and there is usually little trouble about prices for really good animals. Horses are brought here from all parts of the country, and orders are frequently received from Mexico and other foreign countries. Just at present good, matched pairs bring the highest prices. Many of these horses are picked up on farms by buyers who have had an eye on them from colthood. The outlook for the horse market in this vicinity was never better for good stock and never poorer for poor stock.

THERE have been 50 failures among wool dealers in the last eight months and a considerable number of manufacturers of woolen goods have also either closed their works or gone into bankruptcy This great depression in the wool business is uniformly attributed to the present high tariff on the raw staple, and a combined effort is to be made to secure, at the next session of Congress, a great reduction or the entire abolition of import duties on wool. The National Association of Wool Manufacturers has called an extraordinary meeting of that body at Boston on September 17, for the purpose of taking vigorous action in the matter. Isn't it time for the wool-growers of the country also to take prompt and vigorous measures to counteract a growing agitation which seriously threatens their interests? Forewarned should be forearmed.

THE Southern Interstate Farmers' Association which closed its annual session at Montgomery, Alabama, last Wednesday, recommended the absolute discontinuance of jute bagging whenever a substitute can be obtained, and passed a resolution urging the non-use, when possible, of every article which has been placed or shall hereafter be placed under a trust for the purpose of excluding competition. There is no anti-trust law in Alabama; why didn't the assembled farmers advocate the passage of one? The greed of trusts and kindred organizations will never be successfully checked by the passage of mere "resolutions." When the price of any article in common use is raised beyond a certain point, its consumption will inevitably diminish by an unchangeable economic law; and mere resolutions are hardly likely to affect the course or extent of this diminution.

AN observing Michigan subscriber writes that he has learned the following things during the past year.

"I have become convinced of what I have long believed, that, while our Michigan is a wonderful country for grass, the idea of a permanent meadow or pasture is for Americans a delusion and a snare. We have not the warm, moist, almost humid climate of England. I am satisfied the pasture must go. It is the easiest thing in the world to sow grass seed too deeply. I have lived with grasses a good deal the last year, and have noticed many cases of failure of seeds sown in drills, when the same seed succeeded well if sown broadcast and left to cover itself. Clover with oats has again succeeded with us, and the tedder is the best man in the hay field. This last I have known some years. I have encountered land this year that may be worked up too fine for its own good, and have learned that White Clover when not wanted is one of our worst weeds."

THE game laws in many of the States should be overhauled and changed. As at present constructed, they benefit the hunter and the city "sportsman" more than any other class of citizens. This should not be so. The game found on the farms or on lands adjacent to farms ought to belong to farmers or country people. The game laws should have for their prime object the preservation of game for the benefit of those who are most clearly entitled to it. All game laws should recognize the fact that the owner of the land upon which the game is found should have first right to whatever profit or pleasure the game may bring. Many a farmer's boy has manfully refrained from setting his snares for quail or partridge because such action was "against the law," only to see a crowd of "pot-hunters" come marching on the farm the day "the law is off," to conduct their murderous fusilade. The R. N.-Y. wants game laws that will give the farmer first right to the game raised on his land.

WE are informed by a reliable authority that the cruel practice of spaying cows and heifers has been followed to such extent in the Far West as to quite seriously diminish the number of calves. In fact, it appears that so much of this work has been done that the cattle supply from the plains will be not a little influenced thereby in the next two or three years. Men who have watched the Western markets for years inform us that the prospects are unusually bright for better prices for beef cattle. Very heavy shipments are now being made to Europe and there is every reason to believe that this business will continue. In fact, the prospects for beef growers in sections where the dressed beef people come to buy rather than to sell are good. The prospect for hogs is not so encouraging just at present. The supply of hogs at the West seems to be above the average, and if the corn crop turns out to be no better than is now expected, there will be a rush to market the hogs for which there will be no corn. This will surely result in unsatisfactory prices.

THE R. N.-Y. WHEAT CROSSES AND HYBRIDS.

THE R. N.-Y. has very little that is new or interesting to report in regard to its wheat crosses and hybrids. As its readers well know, one of its endeavors has been, by using rye pollen year after year upon the progeny of wheat and rye hybrids, starting with wheat as the mother, to produce a plant which should be rye to all appearances; in other words, to get back to rye through wheat. This trial has come to an end through necessity or through causes "over which we had no control," viz., absolute barrenness of the latest progeny. Several plants were produced with a parentage seven-eighths rye. These the first year bore a few kernels which were planted. The next year, many of the best heads were again treated to rye pollen, but neither these nor the heads not so treated bore any grains. We need not detail our trials further than to say that we are satisfied that any endeavors to originate a hybrid which shall be more than three-quarters rye will prove ineffectual.

For the rest, it may be said that we are endeavoring to fix a number of varieties three-quarters rye, one-quarter wheat, by parentage, with a view to their introduction.

THE POTATO CROP.

A STUDY of the potato reports on page 576, will confirm the R. N.-Y.'s prediction of last week. The Eastern crop is seriously damaged and will be cut short at least one-third, while the Western crop, taken as a whole, is an average one. One feature of the situation is quite significant: The rot seems to be worst in the districts largely given up to potato growing. As a rule, the best crop condition is found this year in localities where the home demand nearly equals the supply. It is true that potatoes may "dig out" better than our correspondents expect. The R. N.-Y. finds its potatoes in better condition than it had reason to hope for three weeks ago. Still, the early death of the vines will cut the crop short and help fill the market with small, half-formed tubers. The crop will be short. Prices ought to be high; who will reap the advantage—farmers or middlemen?

Where does the bulk of the potato crop come from? Is it a sectional crop? It is generally understood that wheat, corn and beef belong to the West. How about potatoes? The question is of unusual interest this year as the rot is confined principally to the Eastern States. The figures we have to present are taken from the Department of Agriculture's report of 1888. It is the crop of 1887 that is given. The Eastern States are Maine, Vermont, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey and Pennsylvania. The Western States are Ohio, Indiana, Illinois, Michigan, Iowa, Missouri, Kansas and Nebraska. The Northwest includes Wisconsin, Dakota, and Minnesota; the Far West, California, Colorado, Oregon, Utah, Washington, Nevada, etc. The total crop of 1887 was 134,103,000 bushels divided as follows.

	BUSHELS.	PER CENT. OF WHOLE CROP.
Eastern States.....	49,861,000	36
Western "	40,846,000	30
Northwest "	18,427,000	13
Far West.....	10,253,000	9
All others.....	14,819,000	12

Most of our readers will be surprised at this showing, we think. How about the demand for potatoes—where are most of them to be sold? It is evident that growers must look to the towns and cities for their best market. Below we give the population of the cities and towns. Remember that this is the *buying* population—the consumers who cannot grow their own produce. We have simply divided the country into two principal sections on a line drawn just west of Baltimore.

Eastern States	7,514,000
Western States	4,632,000

Thus we see that while not one-half the crop is produced east of Baltimore, nearly 65 per cent. of the urban population of the country is located in that section. With these figures for a basis and assuming the Eastern crop to be 65 per cent. of an average, an interesting problem can be worked out.

"Most of us are anxious to turn in the stock where the meadows look fine for feed, but it would be a better plan, if we would only do so, to give the meadows a good top-dressing after mowing, with either barnyard manure or some commercial fertilizer, instead of feeding them off."—C. F. OLMSTED, page 574.

BREVITIES.

OUR horses like cabbage.

THE magazine reviews the present week will be especially interesting to the ladies.

READ Dr. Stewart's views regarding rotten potatoes, how best to preserve the crop, etc., on page 578.

LIMA Beans and melons sell well. Tomatoes sell better than was expected. It pays to have a variety of crops.

WHAT varieties of potatoes will stand the rot best with you? Let us know when you report on the R. N.-Y. No. 2.

THE R. N.-Y. has received seven copies of a recent experiment station bulletin. Is this the way to make up a circulation?

Of all insipid fruit, we will choose Clapp's Favorite as being the most insipid as it this season ripens at the Rural Grounds. No doubt the drenching rains are responsible.

Magnolia cordata is now (August 20) in full bloom, although it bore its usual number of flowers in late May. We prize this tree for its symmetry and ample foliage more than for its flowers.

WE planted our late fodder corn in drills so that the stalks stand about six inches apart. It is now two feet high. Our neighbor, over the fence, planted a few days later. His stalks stand 15 to the foot. The crop is hardly four inches high.

In the country about the Rural Grounds all the potato vines are dead and have been so for a week or more. Potato beetles deprived of this preferred food, are wandering everywhere in search of a substitute. Tomato vines are alive with them.

A perfect season this is and has been for the Great-panicled Hydrangea. It can not stand drought. The panicles are small and the leaves droop. It may be well to remind our readers that cuttings from the new wood take root very readily, and these little plants will not fail to bloom next year and they will bear larger panicles than older plants.

WHAT seemed like a genuine ensilage "boom" was started at the Ensilage Convention at Cleveland last spring. The R. N.-Y. is now informed that not much over one-half the silos that were contemplated will be built. The reasons given are various. This has been an excellent season for hay, a poor year for corn. As the silo depends upon the corn crop and is to remedy a failure in hay, it will be seen that the past season has not been entirely suited to the ensilage system.

At this time (August 20) we may mention the following among our little collection of Tea and Hybrid Tea Roses as blooming most freely. Now is *just* the time when beautiful roses in one's garden, if not worth their weight in gold, are, at least, most highly prized. Marie Van Houtte, Apolline, Perle, Etoile de Lyon, Comtesse de Frigneuse, (a most charming yellow) Caroline Custer, Canary, Madame Hoste, Madam Welche. The new hybrid between Rosa rugosa and Sombreuil, named Georges Bruant, has made a fair growth. Two strong pot-plants were ordered early in the season. Neither has bloomed nor formed a bud up to this time.

A WELL-DRAINED firm seed-bed as level as it may be, with a mellow surface, is the first essential of successful wheat-culture. If the land dishes in any part so that water will stand for several hours after hard rains, the wheat in those places will be injured or killed. Drill in from one to one and three-quarters bushel of clean seed to the acre according to the fertility of the land and the tillering habit of the wheat. Drill it one and a-half inch deep. The R. N.-Y. from its own trials, does not approve of rolling wheat land after it has been sown, if the field has been properly fitted. Whether it will pay or not to mulch the field with fine manure after the ground is frozen, will depend upon circumstances which each farmer must consider for himself, as, for instance, the cost of the manure, the fertility of the land, its liability to heave; etc.

Dairy Husbandry.

THE NEW BUTTER EXTRACTOR.

L. S. HARDIN.

Recent improvements in butter-making; the latest of all gets the butter directly from the fresh milk; much like the centrifugal separator in appearance; how the butter comes; a temperature of from 52 to 65 only needed; extracts nearly all the butter in strictly prime condition; a complete revolution in butter-making; will the fresh-milk butter keep?

Those of us who have kept abreast with dairy improvements during the past 10 or 15 years have become somewhat accustomed to startling innovations. The crocks and pans of our grandmothers first gave way to the large pan that held a herd's milking; then came innumerable devices for cooling the milk with water. Deep setting then made its appearance without the use of ice, and proved a failure. Then cold water and subsequently the submerged practice came to the front as a success. Next in order, the centrifuge made its appearance to supersede all other methods. All of these systems had but one object in view, and that was to obtain the cream, and the improved methods were really but slight improvements on the original crock and can; for where they left off the art of butter-making had but just begun. To get the butter requires about as much skill with the new as with the old process. When the first announcement came that a new candidate for dairy honors was in the field, no one thought much of it until it was known that the claim was to produce pure, first-class butter directly from fresh milk. This was so squarely in the face of all known principles of butter-making that no one credited the claim. Therefore when I was called upon to be the first man to examine and write up this machine, it was with much skepticism that I entered into the "assignment," as news paper men call it.

The machine in outward appearance resembles the ordinary separator so closely that no one would suspect it to be more than an improvement on that implement, and perhaps, correctly speaking, that is all it is; but it is a very remarkable improvement, about as great a one as the modern iron-clad is in advance of Fulton's first steamboat. The milk enters the butter extractor just as it enters the separator and the skim-milk leaves it in the same manner; but instead of a tube at the side for the cream to come from, there is quite a large opening at the bottom of the churn from which the granular butter makes its escape. I say "granular," though by the slight movement of a lever or screw the butter can be made to come quite solid. It begins to make its appearance so soon as the machine gets under full headway. Its revolving speed is about six thousand revolutions a minute, and it has a capacity of 500 gallons an hour. The very intelligent gentlemen in charge say it has five times the creaming capacity of the ordinary separator; that is, it could turn out five times as much cream if the inner wall were removed so that the machine would produce only cream. It could do this while running at the same speed as the separator. This is owing to an improvement in the form of the drum.

The secret of the butter attachment is this: The cream is first separated from the milk and then it finds an additional wall to climb in the center of the drum, and as it reaches the top of that wall, its weight causes it to fall into an inner compartment but it is not yet butter, though it looks like it; there is too much serum or milk in it, and this has been where others have stopped in the attempt to get pure butter. In order to accomplish further separation, a small instrument, like a bird-cage, without top or bottom and without any power to turn it except its own momentum, is placed in the center of the drum and gives just enough agitation to this thick cream to let the last particle of milk out from between the globules of butter fat. These globules then coalesce and form granules just as the butter does in the churn when stopped at the right time in modern practice.

One point struck me as very strange, and I am sorry that the inventor of this machine, Mr. Johnson, had left for Copenhagen before I could get an explanation from him. The ordinary separator in order to work to advantage, must have the milk heated up to among the nineties, a degree fatal to all butter making; but this machine actually does its work with the milk all the time not above 65 degrees. It is claimed that it can work with milk as low as 52 degrees. The only explanation I could get was that all was owing to the improved form of the drum. The claims are that it secures more butter from the milk than any other method, leaving but 99-100 of one per cent. of fat in the skim-milk. This skim-milk is perfectly sweet and in the best condition for drinking or feeding. The butter is as fine as any that ever came under my observation, and is prized equally highly by all with whom I have talked, who have witnessed the machine's work, and they number many of the celebrated dairymen of the country.

It is hard seriously to contemplate the tremendous revolution this machine is certain to accomplish in the dairy. If it did only half what I have seen it do, I would still look to see it drive all other methods out of practice. According to my figuring, done in the rough, of course, it required about 22 pounds of city milk to make a pound of butter, and the butter, as I said before, was as fine as the most masterly artist in butter-making could produce. This it does every time, if the milk is good. Here we see the butter-maker's occupation "gone," for there is no setting of the milk, no curing and tempering and churning of the cream, and hardly any working for the butter, as it appears in perfect granules, is sprinkled with water and most of the milk is washed out of it, leaving it ready to be salted and put in the tub. The person who could not make a fine article of butter with this machine, would have a genius for failure, because he would really have nothing to do with it except to accept the article as it came from the machine.

The objection to sweet-milk butter founded on the fear that it will not keep is to be met by practice, though it is claimed that the granular butter can be washed in sour milk, and that thus the virtue claimed for its keeping principle can be secured. I never was a believer in the sour theory; for I believe that a thing which has never begun to decay will keep better than one that has. I know nothing of the company that has the extractor in hand; but understand that it has already a large number of orders for machines and will soon begin their manufacture.

DAIRY CONFERENCES IN CLINTON COUNTY, N. Y.—I.

Number, location and capacity of the creameries; methods of cream-raising in use; handling the milk, cream and butter; kind of cows; a test for butter; good advice from Col. F. D. Curtis.

Up the Saranac River, 16 miles west of Plattsburgh, 900 feet above the level of Lake Champlain, close to the foot-hills, within sight of the gray walls of Clinton prison, and in the shadow of the Adirondack and Lion Mountains, is a creamery at which the milk from 400 cows owned by 60 patrons, is each morning centrifuged in a Danish Weston separator, milk being delivered but once a day—in the morning.

The creamery is one of six, which with a cheese factory, located at Peru, are owned and operated by Mr. A. D. Boomhower, and all of them are in Clinton County. The creameries are located at Saranac, Plattsburgh, Mooer's, Mooer's Forks, Ellenburgh Center, and Cherubusco Village. The average number of cows for each creamery is about 400. At four of the creameries, or "butter factories," as they are called there, the milk is bought of the patrons, by Mr. Boomhower, at an average price of 80 cents per 100 pounds; at the other two and at the cheese factory the milk is made up for the patrons. The Danish Weston Centrifuge is used at all the creameries except at the one at Ellenburgh Center, where the Burrell & Whitman ice vat system is employed and where, at the time the conference was held—August 8—the best results were being obtained; that is, the largest percentage of butter to that of milk creamed. No doubt this result was due to the better pasture the cows had, and not to any superior advantage the process possesses over the centrifuge, as it is well known that all conditions being equal, the machine will extract more butter fat from a given number of pounds of milk than will any other cream-raising device; but there are many excellent butter-makers and experts who will tell one that butter made from centrifugal cream is not of as good quality, nor will it keep as well as will butter made from cream raised by the Cooley or Stoddard process. They will tell you that it is of too "salvy" a nature with less grain; or, rather, that the machine seems to break the grain, thus leaving the butter in a sticky, salvy condition.

At the Saranac creamery there are now being delivered 7,500 pounds of milk each morning; the maximum, during the "flush of feed," in June, was 9,500 pounds; the ratio on August 7th, was one pound of butter to 24 pounds of milk. No grain ration is now fed by any patron. The pasture is mostly upland, the grasses being wild or mountain. Much of the pasture land has never been plowed or seeded, and is partially covered with a second growth of white birch, poplar, spruce and pine, the original forest having found its way to the charcoal kilns, whence it went into the forges years ago. The water is excellent, being from cold spring brooks, and the cows are salted, usually twice a week, in the stables.

The milk is separated at a temperature of 80 to 85 degrees, and the cream cooled down to 58 degrees as soon as possible. All milk is "pooled;" therefore all the cream is delivered from the separator into one vat—a large one—in which ice is put to keep the temperature of the cream while being ripened at the desired degree, which is not above 60 degrees. The time occupied in ripening is 24 hours, when it is churned by steam power in a Blanchard box churn of 400 gallons capacity, revolved at 50 revolutions per minute. When put into the churn, the cream is at 58 degrees to 59 degrees; the temperature of the butter when the separation occurs is 62 degrees to 64 degrees. Butter is worked on an old-fashioned hand lever worker, and salted with Warsaw salt—one ounce to the pound. It is packed in three, five, 10, 24, 32 and 62-pound packages, as preferred by customers. Nearly one-half of the product is sold to the hotels in the Adirondacks, at an average price of 21 cents; the remainder is packed in 62-pound Welch, spruce tubs, and put in cold-storage in the creamery buildings. There are about 2,500 packages or 155,000 pounds now in store at the six creameries, which will be shipped, it is expected, about the first of November. The cows are mostly natives with a small number of low grades, mostly Ayrshire and Short-horns.

The first special churning done at this creamery was of cream from the dairy of native cows belonging to Mr. Solomon Brelia, one of the patrons, and included 200 pounds of milk, drawn from the cows Saturday night and Sunday morning, mixed at the creamery and centrifuged Sunday morning at ten o'clock. It was put into a tin can, and cooled down to a temperature of 40 degrees where it was kept till 7 A. M. Tuesday, when it was taken out, and warmed up to 65 degrees; at 11 o'clock it was cooled to 60 degrees, put into a Stoddard Churn, which was revolved by hand power at a speed of 60 revolutions. Separation occurred in 25 minutes; buttermilk was drawn off and the butter washed in ice water in the churn until no milk was visible in the water drawn off. Before the butter-milk was drawn off, a small handful of salt was put in the churn, to facilitate separation. When taken from the churn, the butter was in the granular state, the granules being about as large as kernels of wheat. It was salted on the creamery worker, with Warsaw salt—one ounce to the pound—and worked till quite dry. When finished it was pronounced by Mr. W. H. Gilbert, of Richland, under whose supervision the work had been done, as of very good quality. Product 8¼ pounds of butter; ratio, one pound of butter to 24.24 pounds of milk. After dinner, the few ladies and gentlemen in attendance repaired to a large hall near by, where Mr. Gilbert explained the objects of the conferences and told how to raise cream, get the most there is in the milk, set and ripen it; work, salt and pack the butter, preserve and market it and to get the best price for it. Col. F. D. Curtis, of Kirby Homestead, talked to them in his pleasant, familiar way, telling them how to feed, what to feed, when to feed, and the breed of cows to feed to make dairying profitable. The cows must be good ones, of whatever breed they may be; there are good cows amongst the natives, and there are very poor ones, just as there are amongst the "bloods." Not all the Jersey, Guernsey, Holstein, Short-horn or Ayrshire cows are good butter cows. There are *poor* cows in all breeds. Don't keep a cow, no matter of what breed she may be, or how much she cost you, that will not earn a profit. Hunt them out with the scales, and, when you find one that is sponging her living sell or shoot her. Milk only cows that will pay for their board and give you a surplus. Provide warm barns and stables. Seed pastures with milk-producing grasses; rid them of noxious weeds. Give the cows access to salt and plenty of pure water every day. Feed a well-balanced grain ration—cotton-seed meal, wheat bran, linseed meal, pea-meal and ground oats are the best feeds for milk production because they are foods that produce bone and muscle. Build silos; study the science of breeding and feeding. Do not allow your cows to go on strike four or five months of the year. Change largely to winter dairying. Three-fourths of the butter made is made during the months of June, July and August. Results, an over-supply, glutted markets, and low prices; make only butter of the *best* quality, which always commands the *best* prices. Three-fourths of the butter made and thrown on the market is fit only for grease. Don't make that kind of butter. It is just as easy to make good butter as to make poor butter; but to do it you must have clean utensils; sweet, and neat dairy rooms and storage; stables kept free from filth and odors; clean and healthy cows, which must be fed and milked regularly by careful, intelligent help. With such cows and appliances and the adoption of modern methods, you will succeed as a dairyman, making the business both pleasant and profitable; without them you will fail. C. W. J.

Miscellaneous.

CORRESPONDENTS' VIEWS.

Intensive versus Extensive Farming.—The year 1889 has demonstrated more than it has been shown ever before (in the Cotton Belt, at least,) the folly of *extensive* farming and the benefits to be derived from the *intensive* system. Every patch of cotton, within my own observation, that has been fertilized, no matter how poor the land, looks well, though, owing to a six weeks' drought at planting time, we did not get a stand of cotton till June 10, two months later than usual. Since then we have had 45 days on which the ground has been too wet to put earth either to cotton or corn. As a consequence, there are hundreds of acres of both that are given up to grass and weeds, and are a standing monument of the folly of pursuing the "extensive" system. No cotton raiser should plant a greater number of acres than he can cultivate well regardless of seasons. If he will manure what he does plant, he will make far more, one year with another, than by farming on the "extensive" plan. Having less land in cotton, we can plant more in feed crops, keep fatter stock, and more of them, thereby increasing our supply of fertilizers, enabling us to plant a little more every year on the "intensive" plan. G. H. F.

Denmark, Mississippi.

Preparing Corn Ground.—There are many ways of preparing the ground for corn, and each doubtless has points in its favor according to the soil to be planted and the latitude of the locality. But here in northern Illinois we have a method of preparing sod for corn, which is growing in favor, though not generally known and adopted. The sod should not be pastured in the spring as a good growth of grass is one of the chief elements of success. Then from the 10th to the 20th of May the sod should be plowed five or six inches deep with some plow that will cover well the grass and weeds and turn the sod over flat, or at least without kinking and breaking it too much so that it can be harrowed well with a smoothing harrow and a mellow seed-bed be prepared without disturbing the sod and tearing up the grass. We then plant two kernels to a hill about 18 inches apart, in rows one way with a two-horse planter: rows three feet 10 inches apart. A cultivator can be used without tearing up the sod and the corn will respond grandly. We do not plant till the first of June when all danger of cut-worms is past. I have a piece planted the 3d of June, which at the present writing I believe is fully equal to any planted a month before on equally rich land. Many who saw me preparing the ground shook their heads and talked of failure, offering to help me out by giving me some extra early kind of seed corn. But I planted our common field varieties and I begin now to hear words of praise for my nice corn from those same individuals. Our soils are black loose loam on creek bottoms and yellow clay on the ridges. This is a limestone country. There may be nothing worth trying or novel in this for many of your readers, yet it may be useful to some. The most perfect field of corn I ever saw was raised in this way but they went through it once with hoes and twice with a cultivator. W. S. S.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

PILLOW-SHAMS, according to the opinion of most men, are a nuisance and a humbug, yet unquestionably, if one wishes a

regularly-used bed to look always smooth, they must be used. True, a very pretty effect is produced by using a colored spread and a round bolster during the day, the bolster being covered with the same material as the bed-spread, gathered into a frill at either end, and there tied with bows of ribbon. The handsomest of these covers are made of figured draping silk or embroidered satin sheeting, but they are very pretty in figured art muslins, such as are sold for curtains. According to the English mode, the bed-spread is bordered with a frill nine inches deep. Again, the bolster may be covered with colored silesia or sateen—pink, orange and pale green are the prettiest colors—and then the outer covering may be made of fine dotted swiss, frilled at the ends, and tied with ribbon of the same color as the lining. The bed-spread should be of swiss, bordered by a nine-inch frill, and lined with the colored silesia.

* *

STILL, to many people, nothing is so desirable as pure white for bed-covering; in such a case fine muslin shams and a heavy Marseilles spread are prettiest. We care little for lace bed sets; unless of exceedingly good and consequently expensive lace they are very vulgar; often they are much out of place. Similarly, bureau covers and mats of lace and ribbon are pretty enough, yet out of place for moderate purses. It is not only their original cost that is objectionable, but their perishable quality, for once soiled, there is no possibility of renewing them without ripping them apart, at least. Fine linen, open-hemmed and embroidered in washing silk, makes the prettiest and most durable covers for washstand and bureau. The fringed linen covers are very pretty, but the fringe never looks so well after washing as before, no matter how carefully it is laundried. The same may be said of carver's napkins, tray cloths, or beaufet scarves. These three articles last named are very pretty and artistic when the white cloth is embroided in some bold designs with white rope linen, or a mingling of white and gold. The same style may be used for table runners or over-cloths, to be laid on the white damask of the dining-table. An over-cloth of fine white butcher's linen, embroidered in gold or pale green, with a fancy pot containing a low-growing fern in the center, will make a very plain dining-table a thing of beauty.

MAKING COLLECTIONS.

OLIVE E. DANA.

I THINK it is one of the best and happiest recreations that any young person could have—a hobby and a habit in every way safe, wholesome, and delightful—this of making "collections." I was reading the other day in a bit of informal reminiscence, how a popular author, of growing repute, who speaks through his books and from his editorial chair to I don't know how many thousands of young people, treasures still his specimens: a hundred or more birds' eggs, with many nests taken after the birds had left them; an album containing hundreds of postage-stamps, a tray of shells, and minerals, cards, and old coins, gathered all of them in his boyhood.

If I were a boy, I should want almost as many. I should want the birds' eggs, and the minerals, and the coins; and still another collection of woods. A girl might have such collections also, in addition to her herbarium. Who wouldn't rather have such a one, than the most elaborate piece of fancy-work? How much more strength and pleasure would go to the making of it; yes, would *come* with the making of it! And what happy memories would make it doubly precious!

But there is another sort of collection that I wonder young people don't oftener try to get, and that is a collection of books. Perhaps it is the very abundance of books, and the easy access to school and town libraries that make many people so indifferent to the charm of ownership. But the joy of possessing even a few loved volumes has only to be experienced to be appreciated, and is enough of itself to make one long for more, and, once begun, the little library grows as if by magic. One mistake which young people often make, and which helps to discourage effort in this direction, is that of thinking that, as in reading, one must start with certain "standard" works, whether he likes or enjoys them or not. One might adopt and adapt Carlyle's advice to a young student, and say: "BUY the first book you honestly desire to own or read." That will lead on to others, and books so chosen are likely to be valued.

I would not at first, unless my means were very ample, make any pretense of "departments," though I would have, if possible, a variety. And I wouldn't care for so-called "classics," unless I happened to really want them. I am not sure but I should begin with books of and about the present, and perhaps go back from that to the past and come down, after the usual fashion. And I think I should let some of the living writers who know so well how to do it, re-tell to me, with the light of to-day upon them, the old stories of history and mythology, invention and biography.

I should, if my means were small, look for cheap editions, with, however, good print, *always*, and usually serviceable bindings. The publications of John B. Alden, of New York, are excellent, various, and marvelously cheap. I should study his catalogues, and those of Wanamaker of Philadelphia. And I would look for shop-worn copies of desirable works at the book-stores, where space is often given to such bargains. I should be willing to do without other indulgences, I am sure, for the sake of adding to my store, and it would soon be understood, at holiday time, that books are more acceptable than anything else as gifts.

Carlyle advises us to begin with "history, and especially the history of one's native country." And I think I should like among my books, after I had secured a few "must-haves" in the way of reference, etc., and maybe a volume or two of poems, some works of American history and biography,—for biography tells history, we all know, in the most graphic and readable way.

Both are combined in some of the volumes of the "Riverside Library for Young People," published by Houghton, Mifflin, & Co., of Boston, at 75 cents per volume. Two of the series are especially to be commended: Mr. Horace E. Scudder's "Life of George Washington," and "The American Revolution" by John Fiske. And there are other biographers that help to tell the story of our country, and make good reading, also:—the lives of Benjamin Franklin, of John Adams, of Lincoln, Grant and Garfield, of Clay and Sumner and Daniel Webster; and I should want sketches of authors, too. Mrs. Bolton's "Famous American Authors" is one of the best of such books; and still another pleasant volume is Mr. Riding's "Boyhood of Living Authors." I would not reject altogether "paper covers." I have some which have done excellent service for years. I know of more than one such series in which valuable works are issued. There are some excellent ones in the "Riverside Paper Series," representing really famous authors as well as popular ones. One of Mr. Aldrich's stories comes in this series; one of Hawthorne's most famous and powerful works; one also by Prof. Hardy, with more to follow. Roberts Brothers had an inviting list in paper covers last year, which is probably continued; and the Lippincotts issue some very desirable things in cheap compact form. One would not buy many, of course, in unsubstantial binding, but a few, well chosen and carefully kept, are not amiss.

WHAT AILS THE BABY?

MRS. G. H. ROWELL.

"DO you think my little darling is sick?" said Mrs. Watson, as she seated herself in a camp chair, on Mrs. Williams's porch. "He cries all the time; I do not get one minute's rest in the whole 24 hours; the doctor says he is well enough, and it is only a habit he has got into. I give him soothing sirup, but he does not sleep over five minutes at a time. I do believe he will wear me out," and the poor woman drew a weary sigh, as the little eight-months-old babe set up a stentorian yell.

"He has strong lungs, any way," said Mrs. Irving, "let me take him a few minutes and rest your arms. I wonder if the little fellow is thirsty," and she carried him into the dining-room, to get a glass of water, followed by his mother, exclaiming:

"Oh, Mrs. Irving, do not give him water, it will give him the colic, sure."

"Not give him water! Why babies ought to have water, I always give it to mine. I believe that is what makes him fret. Just let me give him a drink, and if he has the colic I will come and take care of him. Look here, see how he craves the pure cold water," and the little fellow greedily clasped the goblet, and drank freely. "That is plenty for once; I hope baby's mamma will not think that water will hurt him again; it is better than a dozen bottles of soothing sirup; that makes him feverish. I think babies often suffer for the want of water, their little throats get parched and dry, and when they are teething they have fever in their mouths, and they need water."

She sat down with the little one on her lap. Mrs. Watson wiped the perspiration from her face, exclaiming:

"What a warm day! I do suffer so much from the heat this summer! The baby is so hot all the time. I declare he is going to sleep with you! What a wonder!

"It seems as if you had a good deal of clothing on him for such a hot day," and she raised the embroidered dress skirt, and then a ruffled cambric skirt, an embroidered flannel one, and a foot blanket! She actually screamed with astonishment.

"Why, Mrs. Watson, I do not wonder the baby cries! You or I would cry and fret if we were bundled up in this way such weather as this. Poor baby! How he must suffer with the heat! And he ought to be in short clothes, so he could kick and have the free use of his feet and legs. I do not wonder he cries. I should in his place."

"I hate to put him in short dresses; babies look so sweet in long robes. I supposed little ones ought to be dressed warmly."

"Of course, in cool weather; but I should not want to roast them, and such a weight of clothes must be burdensome too." said Mrs. Irwin, as she adjusted the carriage pillows and laid the little fellow down on his side; his mother looking on.

"Oh please, Mrs. Irving, lay him on his back, I always lay him straight."

"What for? It is not a natural position to rest in. Babies always rest better lying on their sides, as well as other people;" said Mrs. Irving. "He will not need anything over him, it is so warm!" Sending back the bright Afghan to his mother.

"Why, you have such queer notions about taking care of babies, I hardly know what to think; it is all so new to me."

"I have had a good deal of practice in raising little ones, and I have been quite successful too, and I think the best way is to keep them comfortable and happy; give them what they need, and what nature craves. I should take off this child's petticoats, and get him into short clothes immediately. Give him cold water to drink when he is fretful, and do not give him medicine to keep him quiet, I do not believe in dosing little ones."

"I must go, but if baby has the colic remember your promise;" said Mrs. Watson as she started the carriage off the porch.

"I will, but if I do not come till then it will be quite a spell before I return your call. He is resting very quietly, you see."

GOLDEN GRAINS.

THE SUNDAY SCHOOL TIMES says that the Christian life is, in all its details, a life of duty. Every act must be measured by the standard of duty. We must, or we must not. If we have habits which we do not feel it our duty to give up, then they must be habits which we ought to feel it our duty to keep up. What it is not your duty to do, it is your duty not to do.....

GOOD HOUSEKEEPING reminds its readers of the fact that secrets are poor property; if you circulate them, you lose the interest of your investment.....

INGERSOLL says that the source of vanity is from without—of pride, from within. Vanity is a vane that turns, a willow that bends with every breeze—pride is the oak that defies the storm. One is cloud—the other rock. One is weakness, the other strength.....

MANY a mother, by the usefulness of her life, fills her children with a desire to be like her, and this desire makes them in their turn unselfish. There are obscure men and women who hardly in their lives utter a word of preaching, yet by their example, they do more to make people around them gentle, truthful and Christ-like, than any 10 who preach but do not practice. It is not those who talk about goodness, but those who are good, that are the light of the world.....

GLADSTONE says that "Darwinism has not been proved to be anything more than a misty idea—the indefinitely shaped outcome of extravagant and idle theorizing." Ruskin speaks of it as a "dim comet wagging its useless tail of phosphorescent nothing across the steadfast stars."....

NOR did such a "hater of ill-grounded old opinions" as Carlyle see anything reasonable in the theory.....

"A good sort of a man is this Darwin, and well meaning, but with very little intellect. Ah, it is a sad, a terrible thing to see nigh a whole generation of men and women, professing to be cultivated, looking round in a purblind fashion, and finding no God in the universe. I suppose it is a reaction from the reign of cant and hollow pretence, professing to believe what, in fact, they do not believe. And this is what we have got to. All things from frog-spawn; the gospel of dirt the order of the day! The older I grow—and I now stand upon the brink of eternity—the more comes back to me the sentence in the Catechism which I learned when a child, and the fuller and deeper its meaning becomes, 'What is the chief end of man?—To glorify God, and enjoy Him forever.' No gospel of dirt, teaching that men have descended from frogs through monkeys, can ever set that aside."..

Contentment abides with truth. And you will generally suffer for wishing to appear other than you are, whether it be the richer, or more learned. The mask soon becomes an instrument of torture .....

MR. MOODY has received from William Mackinson, Scotch shipbuilder, a model of Solomon's Temple made of cedar, overlaid with gold, with many of the smaller articles of solid gold. It is one fifty-fifth the size of the original, having the court, tabernacle, altar, laver, ark, holy of holies, mercy seat, and cherubim in proportion to each other....

ISN'T the Church too often looked upon as an ark of safety rather than as a life boat to rescue the perishing? Stanford says: Only the waters in the ship can sink the ship; but while kept outside, all the heaving deep waters thundering over three-fifths of the globe can work no shipwreck So, while kept outside the Church, the floods of ungodly influence can only help to float it on its voyage of glory, or to lift it to its Ararat of rest.....

Domestic Economy

CONDUCTED BY MRS. AGNES E. M. CARMAN.

"What good to think and then allow
Our gathered thoughts to slumber,
And have our heads, like old cock lofts,
A store for useless lumber?
What signifies philosophy
If we the while abuse it?
Far better have good common sense,
And know well how to use it."

A FEW OBSERVATIONS ON "TABLE MANNERS."

I HAVE often noticed that sometimes parents who are themselves well-bred and naturally refined will allow their children to grow up without some of the most ordinary, the very simplest table manners.

One instance last winter in particular I recall in which the mother, an old schoolmate, a quiet, unpretending woman belonging to an old family, had always moved in good society and was surrounded by all the grace and culture which wealth can bring.

Her daughter, a strong, healthy girl of 15, had without any exception the least idea of the table manners generally in vogue even among the poorer classes, in this enlightened day. As an elderly gentleman, who had noticed the bright, happy girl, fresh from an exciting game of lawn tennis, remarked: "With the right training she will develop into a fine, intelligent woman." In the afternoon Maud had freely given us her opinion for woman's position in the professions like most modern girls, and had declared her intention to study law. But at the dinner-table that evening Mr. Morgan's illusions were dispelled, for a more gross, coarse manner than she displayed I have never seen. The child was strong and healthy, had an excellent appetite, which could have been readily forgiven, save for her method of gratifying it.

Meat, vegetables, fruit, sauce, jelly, sweetbreads, everything through the entire list did she crave, together with bread and butter ad libitum, which, freely translated, means without a limit—she buttered her whole slice of bread unbroken. Everything within her reach she captured.

"How do you like my friend, Mr. Morgan?" laughingly asked the young lady of the house, as they strolled out to the tennis court.

His well-bred, kindly face lighted up with a polite smile, which hovered dangerously between disgust and respect for the guest within her gates.

"Do you wish to know?" he said at last. "My dear Mrs. Moore, your friend has a sweet, intelligent face and will make a grand success of life, but, pardon me, her manners were—" the good breeding of his fathers for generations triumphed, and only a shake of his head finished the sentence.

And I sadly acquiesced, knowing she had

Miscellaneous Advertising.

When Baby was sick, we gave her Castoria.
When she was a Child, she cried for Castoria.
When she became Miss, she clung to Castoria.
When she had Children, she gave them Castoria

fallen too low in his good opinion ever to rise, despite her future achievements, unless her manners were very materially improved.

This have I actually seen, and now let me give you a pen-picture of another family—a family of almost ideal manners. Mrs. White has five children, a mature son and daughter, one son 16 and two girls of 12 and 14. None of her children were allowed to eat at the family table until they were 10 years old. Before that they ate at their own table in the nursery, presided over by the nurse and often the mother or elder sister would join them. Here they were taught simple, easy manners, and sometimes papa himself would look in a moment at them during their early dinner hour. They were always told that when they were 10 years old they could eat at papa's table down in the dining-room, and I believe in cases of good behavior they were allowed to eat with papa at dinner on Sundays from their eighth year. They were taught to take their places quietly; bow their heads while the blessing was being asked; the use of their napkins and forks; to use the spoon only when necessary: the knife never save for carving, or spreading butter; to sit quietly; to understand that mamma's "No" was final, and never to pout at or dispute her decision on any coveted dish; never to drop anything, but in case of an accident to say: "Excuse me," and to pick up the silver or food which had fallen, never to say, as one little child did at a ceremonious dinner: "I dropped my cake mamma, and it is dirty."

If the household pets are allowed in the dining-room, never permit the children to feed or caress them during a meal, but have a rug or a special corner where they may lie. They will soon learn this and both dogs and masters will thus learn a useful lesson in manners and obedience.

One of the maxims of our house is that good manners are not to be put on with the dainty "best" dress in honor of some guest, and then carlessly laid aside until on the next occasion when required the dress will be found to need a few stitches, a fresh braid or clean ruche—in a few hurried moments the garment may be repaired. Here the comparison ceases, for good-breeding should become an essential part of a person's individual character, never to be brought out only on great occasions. If all the members of the family would endeavor to be as truly polite, as kind, as thoughtful to each other at the table, as they would wish to appear before strangers even the most unruly dinner group would gradually come nearer to making the meal that ideal we all are striving for—a quiet, restful repast—where all down to the little golden-haired "girlie" bring their best thoughts, feelings and aspirations. And the trials and vexations of the day if not half effaced, are not mentioned. Such were the dear, old gatherings at the close of the day, in my mother's home in those far-off years. Those who made them such are scattered now, father and mother having gone to that "other home" and brother and sisters out in the world. And thinking of that dear old home I often remember that favorite hour and the lessons our mother taught us there. Perhaps a weary, over-burdened mother is now almost despairing over her several little ones because her rules are so often broken or forgotten, and there seems no improvement.

Let me help as well as criticise. In the room which was once my nursery there still hangs as a guide an old, simple and concise proverb, painted on heavy cardboard, which has been the rule, the inspiration of my two children since their childhood, first in table manners, and in their older days in all the trials of life. It is taken from the Greek, written several hundred years before Christ.

"Trying will do anything in this world." Here is another idea I learned the other day. A novel plan which may help many a mother, —which should help I ought to say. The motive is taken from Longfellow's beautiful poem entitled "St Augustine." It consisted of the first verse only.

> "St. Augustine! Well hast thou said,
> That of our vices we can frame a ladder,
> If we will but tread beneath our feet
> Each deed of shame."

In my friend's large, pleasant, cool nursery on her black-board which is a constant source of enjoyment to her children, there were drawn with crayon three ladders, one for each child. There are only seven rounds or "steps" to each ladder, when completed, one for each day in the week. At the end of the day if the fault or "sin" had been conquered, a "step" was added, but if the fault had been committed, the round was omitted from the ladder, the space being left vacant as though broken. I should have said that over each ladder was written the name of the special fault which the child wished to correct. The name was changed occasionally. This time it was "Table Manners."

Every Sunday, Mr. Herbert, with happy, careless Ted, grave, sweet little Madge and little Comfort, (the baby), made their way to the room where the children showed papa their "ladders," sometimes with bright sparkling eyes and occasionally with tear-stained faces and mamma was close at hand to give her counsel. I remember one occasion when conscientious, little Madge as she clung to her fathers hand, said with a sob: "Papa, I tried and tried 'most every day." "Papa" tossed her up in his arms, kissed her and told her to keep on trying, and remember that papa always loved her whether she succeeded or not, "But Madge does try," the little thing repeated. "Mamma says I'm like you. I try to do my best—and Ted forgets sometimes," in a half whisper. Papa carried the children down into the library, where he read them a chapter and told them stories of that beautiful "Child."

I would especially caution mothers not to take their children visiting until they reach a suitable age, unless they have early cultivated good manners. Many a family has been annoyed by the children of a guest, who have never been taught self-restraint or self-government, and who by their loud boisterous ways remind one vividly of a half-starved animal and often completely spoil an otherwise enjoyable meal.

Do not think that I dislike hale, hearty children. An enormous appetite is no disgrace, but rather a blessing to its owner, but it may be quietly and properly appeased. Until children reach that suitable age, I would advise all mothers to let them remain at home while they should themselves visit their friends unaccompanied. If this is not possible they should give up the coveted "outing" rather than inflict the petty faults and grievances of their children on friends or relatives—it matters not which.

Only our virtues, not our vices, do we elderly people strive to carry to a friend's home, and why should not our children be early instructed in "good manners," not the least valuable of which are "table manners?" I have said nothing of technical "etiquette," having confined my remarks to ordinary, simple, good breeding for the dining-room.

REBECCA NEWCOME.

BOARDING AGENTS.

SOME time ago I saw in a paper (I think it was the RURAL) among other suggestions for bringing a revenue to farmers' wives, the keeping of traveling agents for pay recommended. The writer's experience must have been very different from mine, or else different kind of men travel in our locality.

Often a peddler of tinware will be allowed to stop over-night, or to dinner, who seems to expect to pay for the entertainment of himself and horse out of his goods. Very many of them get their bill for half or a third what they would have to pay at the nearest hotel; then the man puts about three prices on his goods, which are apt to be of the poorest quality, and will hardly keep their color until he gets out of sight, and that is his way of making an honest living. He is generally paid by the day and his employers allow him a certain sum for his expenses, but he contrives in this way to keep the lion's share of it.

A friend of mine once kept a vender of pictures and maps over-night. After breakfast he asked what was to be paid, and the farmer told him that if he had anything in his collections that his wife would like, he might settle it with her. But anything she wished for, was so extravagantly high-priced that the farmer's wife said to him that she might better give him his bill entirely, than pay the difference between that and his goods. "O thank you very much; much obliged, I am sure," said the greedy peddler and at once departed to seek new subjects to prey upon

A year or two ago a couple of agents came into a certain neighborhood, canvassing for Bibles. They put up with a farmer whose wife was doing her own work, and had quite a family to care for; they engaged to board and lodge with her while they went through that part of the town, and told her to put a good price on her work. That ought to have put her on her guard; but it did not, and after getting all the subscribers they could, they took her husband's order also for a large Bible, at a war price too, and they were to deduct two dollars from the price of the Bible when it was delivered, and pay their bill at the same time. However, another man delivered the Bibles they had got subscribers for, and the lady was out her board bill and had to pay full price for her Bible, as, of course, rascal number three did not know anything about that little arrangement which the others had made. If that was not highway robbery it was something worse.

Among the traveling agents there are stock and poultry buyers, who will insist on paying for their dinners. Many such are farmers, and know how it is themselves; but a farmer's wife who expects to get pocket-money by keeping agents of any kind is building on the sand. A hook on the screen door is her best protection against all such gentry.

AUNT RACHEL.

COLDSLAW.

BEAT the yelks of two eggs, add a table-spoonful of cream, a small tea-spoonful of made mustard, a tea-spoonful of sugar, pepper and salt to the maker's taste. Put a-half tea-cupful of vinegar over the fire to heat, thicken with a small tea-spoonful of corn-starch, and when it boils remove from the fire and add the above ingredients. Cut the cabbage very fine and pour the mixture over.

COOK.

LAMB CUTLETS.

TRIM the pieces free from fat, and flatten out, if necessary. Beat two eggs, add a little cracker dust, season with salt and pepper, dip in the pieces of lamb and fry slowly in beef drippings until thoroughly done.

MRS. J. G.

HOW TOMATO CATSUP IS MADE AT THE RURAL GROUNDS.

ONE bushel of tomatoes, washed, drained, and cut in half. Put over the fire in a large kettle. Add three large cupfuls of salt, two even table-spoonfuls of Cayenne pepper, two ounces of whole allspice, two ounces of whole cloves, four ounces of grated nutmeg, two ounces of stick cinnamon. Boil slowly two hours. Cool and press through a fine sieve, carefully rubbing through the pulp. Put back to boil slowly for three hours. Care must be given it that it may not burn. Bottle, cork and seal, and stand in a cool place. The proportions here given make an excellent catsup, but as we usually make about 60 pint bottles, we vary the ingredients, adding more or less spice. To some, we have added onions and to other bottles Worcestershire sauce. We have just made some that is strong with garlic, and as the head of the house is especially fond of this flavor, he pronounces it "the best ever made," and declares that of all the ingredients added to tomatoes in catsup-making garlic ranks first. Bottle while boiling hot.

News of the Week.

HOME NEWS.

SATURDAY, August 24, 1889.

THERE is extreme distress among the coal-miners in Spring Valley, Northern Illinois. For refusing to accept the starvation wages offered by the "bosses," they were locked out on April 30, and have been compulsorily idle ever since. Several deaths of women and children have occurred from sheer starvation, while the miserable fare which all have had has been a prolific cause of disease and death. Several times large numbers have been saved from absolute starvation by the charity of neighboring towns, and notably of Chicago. Women are now scattered in bands seeking help through the surrounding country..... Mahone has been nominated by acclamation as the Republican candidate for Governor of Virginia. There appears to be much less discord than usual among Virginia Republicans, and from this and the character of the man in the saddle a very lively campaign is a foregone conclusion.....After much bother, the United States Commissioners to the Chippewa Indians have succeeded in their negotiations for the purchase of 3,000,000 acres of good farming land in Minnesota. This, too, will soon be thrown open to settlement... The Oklahomites, in Territorial Convention assembled at Guthrie last Wednesday, earnestly memorialized Congress for speedy legislation for the protection of the people. No laws now exist for making or probating wills; for caring for sick, insane or blind; for constructing or maintaining public works; for levying any taxes whatever; or for punishing any crimes except those against the United States..... That perennial pest, L. Gardner of Chicago, who lately swindled the public out of $30,000 by a bogus lottery scheme, has just been arrested at Dixon, Wy. T., for fraudulent use of the mails.. .....A professor in the California University, claims to have discovered a method of tanning leather that makes it impervious to water and so pliable as to be almost indestructible.....President Harrison has been enthusiastically received on his Western trip. He is now safe at his old home in Indianapolis.....It is getting to be a pretty general opinion that one of the best selections the President made for his Cabinet was "Uncle Jerry Rusk." Besides managing his Department in first-rate style, he has been popular with all his colleagues and the general public from the first, and his popularity has been steadily increasing without a break..... The latest reports from Hayti indicate that Legitime has almost reached the end of his rope, and must soon surrender to Hippolyte or "go." News from the Black Bepublic is so contradictory, however, that one has to guess at the truth. The French and English are contending for paramount influence; what are the United States doing?.....Before 7:30 o'clock yesterday morning four murderers were hanged together in the Tombs Prison in this city—a pretty good showing for a place in which criminals openly boasted, a few years ago, that hanging for murder was played out. There would have been a fifth were it not that Governor Hill respited him for 60 days at the last moment, although one of our best judges, on the same day, decided that there were no grounds for a new trial.... The location for the World's Great Fair in 1892, is still an exciting question. New York, Washington and Chicago are still the most prominent claimants in about this order, with St. Louis a good fourth. Committees to carry on the agitation and raise the necessary funds have been appointed in all four places, that of New York, of course, transcending all the others combined in the prominence and wealth of its members. To make the show what it ought to be will cost from $10,000,000 to $15,000,000. Washington will want the whole amount or thereabouts out of the National Treasury, Chicago and the other claimants would want at least half of the sum from the same source, New York proposes to contribute the whole herself. Congressional sanction is indispensable to an International Exposition, inasmuch as notification must be sent to foreign nations through the General Government, whose duty it will be to solicit foreign co-operation. The South strongly favors Washington; the West is divided between Chicago, St. Louis and New York, with New York as the second choice of the sticklers for the two other places; the Middle and Eastern States support New York. On the whole, New York is likely to get the show if sufficient money shall be promptly raised to distance all competitors..... .... The Knoxville, Cumberland Gap and Louisville Railroad is a new road. Last Thursday the first train to go over it started from Knoxville with a select excursion party consisting of the City Council, Board of Public Works, representatives of the Chamber of Commerce, and the flower of the business and professional men of Knoxville, in two passenger cars. At Flat Gap, 22 miles from Knoxville, at 10:30 A. M., the train went through a defective trestle and of 65 persons on board 41 were injured. Three are dead and others are likely to die. Help didn't come till 4:30 P. M., and the sufferings of the exposed and helpless wounded were heart-rending..... Henry George threatens to conduct a single-tax campaign all over the country..... There's a strong movement on foot in the South to make January 19, the birthday of Gen. Robert E. Lee, a public holiday. The lower house of the Georgia legislature has passed a bill to that effect without a dissenting vote, and the Senate will undoubtedly take similar action. Some of the papers propose that Congress should make it a National holiday. While Northern papers are generous in their acknowledgments of the many personal virtues of Gen. Lee, they scout the idea of a National holiday in commemoration of him, and find numerous objections to a sectional one. Such a celebration of the birthday of Lee, say they, would inevitably be a celebration of the Lost Cause..... The Fourth Annual Minneapolis Exposition was formally opened Monday, and promises to be a Western—that is—a great success..... .....Monday a ramshackle, flimsy, tenement house on Seventh Avenue in this city, in which 75 persons were kenneled, proved a death-trap for 10 of them. It "mysteriously" caught fire in the kitchen of a fellow who was on the eve of bankruptcy, and had a big insurance on his place.....The debts of Sherman Brothers, grain thieves of Buffalo, amount to $355,000; their assests to possibly $7,000.....A Chicago organ of the Knights of Labor gives the membership now at 600,000 against 300,000 a year ago and 600,000 three years ago. The "deserters" have mostly joined other labor organizations, chiefly the Federation of Labor.....New York City has just placed a heavy loan, to run from 18 to 30 years, at three per cent., and so lively was the bidding that premiums ranging up to 2½ per cent. were obtained. Plenty of capital must be waiting for an assured investment even at a low rate of interest.....At Rockland, Ill., there's a flourishing white community under the complete control of George Schweinforth, who is proclaiming himself not only Christ but God. Religious fanaticism in this country is not a monopoly of the Southern blacks ..... Two more Canadian sealers have been seized by the Rush in Behring Sea and sent to Sitka with a comical prize crew of one man on board of each. They'll no doubt follow the Black Diamond to British Columbia instead. Two others were boarded, searched and permitted to go. This whole business, as at present conducted, appears provokingly farcical. The lease of the Alaska Commercial Company giving it a monopoly of seal fishing in Alaskan waters expires next year. Most of the stock is said to be held in Germany.. . . ..Wednesday the largest tobacco auction sale ever made in this country or the world, was made at Louisville, Ky. Amount 1,002 hogsheads, or 1,500,000 pounds, worth over $100,000.....There's a growing agitation for a great State Park in the Adirondack wilderness. This it is said is the only means of preventing the speedy destruction of the great forests that cover the sources of the Hudson River, by the insatiable greed of corporations..... Under a late ruling of the Interior Department dishonorably discharged soldiers in the late war may secure pensions. Many old pensioners object to being thus placed on the same footing as thieves, cowards, cut-throats, deserters and bounty-jumpers. The new rule, however, will greatly help to reduce that bothersome surplus.... The Dominion Government is urged to do something to prevent the large exodus of Canadian female help to this country. Besides the large number of Canadian women and girls in New England factories, it is said 47,957 are in domestic service in Massachusetts alone.....It is estimated that the capital nominally invested in the various concerns in this country dependent on electricity for their business, from the Western Union Telegraph Company down to the humblest maker of electric appliances, amounts to over $600,000,000. This means that we now pay an annual tax of between $35,000,000 and $40,000,000 for a convenience which was not in existence half a century ago.....Miss Huntington, the pretty and ambitious adopted daughter of Collis P., the great Pacific Railroad $75,000,000 mogul, is reported to be engaged to Prince Francis of Hartzfeldt Weldenberg, an impecunious German noble of a fine old spendthrift family. It is said that he expects 4,000,000 francs from Huntington's hoards to pay off his debts; besides enough to live on generously for the rest of his life..The Agricultural Department, Washington, D. C., was closed Monday out of respect for the memory of Ex-Commissioner Watts who died the other day at Carlisle, Pa. He was one of the best abused men in the country during his term in office; still he had lived an honorable, useful and respected life ever since, just as he had done before his appointment ..... The late forest fires in Montana, extinguished by heavy rains during the week, are reported to have swept over from 8,000 to 10,000 square miles. The September fires in the Michigan pineries in 1881, ravaged only 2,000 square miles; but 15,000 people were rendered homeless and 200 lost their lives. The human suffering in Montana must have been much less, as the region was very sparsely inhabited; but the national loss of timber must have been greater.....Besides the large number of Chinese who illegally make their way into this country from Canada and Mexico every year, many come in by means of fraudulent habeas corpus writs at various ports. Records show that 168 entered San Francisco alone in this way since January 1, in spite of the Scott Chinese Exclusion Law.....John L. having been taken down to Mississippi, tried there, convicted and sentenced to one year's imprisonment, was released on $1,000 bail on appeal to the Supreme Court, which doesn't sit till next February. The Big Slugger at once returned to New York and Boston, and with a lot of other athletic notabilities will soon start "on the road" to "coin money." Kilrain was arrested in Baltimore, released on bail, and has started South for trial..... The Morris Park, the finest race-course in the world, was opened in Westchester County just on the north of New York City limits, last Tuesday. It belongs to John A. Morris, the chief owner of the great New Orleans lottery swindle, and cost $1,500,000, and $250,000 more are to be spent in perfecting all the arrangements. The land alone cost $300,000, and there's a dispute with this city as to the ownership of a small strip of it. The New York Jockey-Club has leased it at a rental based on five per cent. on the capital invested. For the the opening meeting, which began Tuesday, $86,000 were put up in purses. The grand stand, stables and other structures are the finest connected with any such an institution in any part of the world.....The Terry-Nagle-Field tragedy still agitates California and interests the rest of the country. The killing occurred in San Joaquin County of which Stockton is the county-seat, and Nagle was locked up there after the trouble. Terry has more friends in that section than anywhere else, and, like himself, most of them are of a reckless class. It was feared that some of the turbulent element might attack the jail, so the imprisoned deputy-marshal was spirited away, in the gray of the morning, to San Francisco, on a writ of habeas corpus issued by Judge Sawyer of the United States Circuit Court, holding United States Court there, together with Justices Field and Swain. The case was thus taken from the jurisdiction of the State to that of the United States Courts on the ground that Nagle was a United States officer who merely did the duty officially confided to him in protecting Justice Field, member of the United States Supreme Court, the highest Judicial Court in the world. Whether the case will come before the State or the United States Court will not be decided for some time, as the matter will doubtless be taken for final settlement to the Supreme Court at Washington. In any case Nagle is certain to get off scott-free according to the demands of public opinion everywhere. In her frenzy for revenge Sarah Althea Hill-Terry obtained from a partisan addlepate judge a warrant for the arrest of Justice Field on the ridiculous ground that he was a member of a conspiracy to kill her husband. He was at once released on bail by Judge Sawyer. Terry appears to have had property worth about $100,000, which, it is thought, he left to his wife. If so, his son will contest the will on the ground of undue influence. He attributes his father's death to the constant goading of Sarah Althea..... Wails, groans and execrations still come from the afflicted Conemaugh sufferers. The $300,000 with which Governor Beaver was to clear up the valley are expended, and the cellars of over 100 houses in Johnstown are not cleared out, and it is expected that nearly 100 corpses together with other disease-engendering matter are buried there. Several dead bodies are still found every day or two. Over $1,500,000 still remain to be distributed. The interest on the contributions would average over $25,000 a week; who gets it? Houses have been built from the charitable funds by contract labor at Pittsburg and Chicago and put up by imported labor in Johnstown, while resident workmen have been undergoing pauperization from lack of work and consequent necessity of depending on public charity. Even the clearing up of the valley and several other public works have been done principally by imported labor. Pittsburg and Philadelphia merchants have been enriched by the wholesale purchase of goods, while local dealers have been starving because the Commissioners would buy nothing of them, nor would they distribute any of the hoarded charity of the world among those for whom it was intended, so as to enable the latter to patronize local dealers and help to revive trade. A trifling saving was doubtless made by this course, but the best way of disposing of the charity would have been to help the people to help themselves. A large staff of clerks, etc., has been kept at big salaries, and any amount of figuring and tabulating has been done, but little real work. The official nincompoops have mistaken bookkeeping for benevolence.....

There is no use in Dodging.

There's no use in dodging, you can't avoid a plump issue; especially one that comes so straight at you as this.

We say—Compound Oxygen is remedial and revitalizing; now observe what our patients say of us:

ST. PAUL, MINN., March 20, 1888.
"For giving the system permanent vitality and the elimination of disease I believe Compound Oxygen to be far in advance of all medicine or treatment. H. H. COOK.

WEATHERSFORD, TEXAS, April 1, 1888.
"You have my heartfelt gratitude for the good your Compound Oxygen has done me."
MRS. FRANKIE EDWARDS.

INDEPENDENCE, OREGON, Feb. 6, 1888.
"Compound Oxygen has done wonders for me. Where there is life it will act like a charm." PROF. J. S. HENRY.
Brown's University.

PROVIDENCE, R. I., March 21, 1888.
"Unquestionably Compound Oxygen is a marvelous remedy. Innocent looking, mysterious in its action, but certainly effective."
P. F. JERNEGAN.
MATTHEWS, N. C.

"My health is now better than it has been in five years. I have about one week's supply of Compound Oxygen, and think I am about well. I owe a debt of lasting gratitude to you." REV. J. A. LEE.

HUMANSVILLE, Mo., Feb. 14, 1888.
"Compound Oxygen has been of incalculable benefit to me. I don't like to do without it." H. A. MOORE, Editor of *Dawn*.

We publish a brochure of 200 pages, regarding the effects of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia; all chronic and nervous disorders. It will be sent, free of charge, to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa., or 120 Sutter Street, San Francisco, Cal.—*Adv.*

FOREIGN NEWS.

SATURDAY, August 24, 1889.

IN the British Isles during the last month, the greatest public interest has been centered in the fate of a worthless woman—a Mrs. Maybrick. She is an American, who married a Liverpool business-man, proved grossly unfaithful to her marriage vows and poisoned her husband to be able all the better to enjoy her paramour. She was tried for murder the other day, and was defended by Sir Charles Russell, the best pleader in the United Kingdom. With no hesitation the jury found her guilty, and the Judge—one of the ablest in England—fully agreeing in the justice of the verdict, sentenced her to be hanged on August 29. While the vast majority of the people fully agreed with the judge and jury as to her criminality, a very respectable minority believed, not that she was innocent, but that her guilt had not been proved beyond doubt. It was shown by a number of respectable professional men on the witness stand that her dead husband used to take arsenic as a medicine; that the amount found in his stomach would not necessarily have caused death, and that the symptoms during his sickness might be those of an ordinary disease. The case was exhaustively and excitedly tried in the newspapers and debated everywhere; reams upon reams of petitions poured in upon the Home Secretary asking for a commutation of sentence or a full pardon. The long-haired men and the short-haired women and all sorts of enthusiasts and cranks, together with a large assortment of professional and business men and others, joined in the clamor against the verdict. Excitement grew to white heat across the Atlantic and the submarine cables became hot with the electric transmission of every phase of the case to this country. Home Secretary Mathews, himself a distinguished lawyer, after careful consultation with trial Judge Stephens and other eminent lawyers, as well as with notable doctors, finally decided, last Wednesday, to recommend Her Majesty, the Queen, to commute the death penalty to imprisonment for life, not because there was any moral doubt of the woman's guilt, but because there was some doubt that it had been legally proved. The public received the announcement of this issue to one of the most notable criminal cases of modern times, with general satisfaction..... Other transactions in the United Kingdom of late have not much interest for Americans. In Parliament the Irish question, in one or other of its multitudinous phases, has occupied more time than any other—nearly as much as all others combined, indeed; so that the sittings must be extended beyond the usual date to complete the votes on indispensable appropriations; while much needed legislation for the rest of the country has to go to the wall..... Agitation has suffered no diminution in Ireland. William O'Brien, the chronic prisoner for patriotism, is again on trial for holding, in County Cork, a Nationalist meeting which had been "proclaimed" under the Crimes Act, and with him is James Gilhooly, his fellow member in Parliament from the County. ... .Strikes are of course, still perennial in the coal districts in the north and in the iron districts in the center of England, and there's a strike of 10,000 dock laborers in London, besides many minor ones in different parts of the country ..... The Government, although now in possession of the most powerful fleet the world has ever seen, is pushing on the construction of new war vessels as fast as possible. Fifty were added to the fleet last year; and the national dockyards are alive day and night with the work of repairs and construction. Moreover, all the new steamers that carry the British flag to all maritime parts of the globe are liable to pass into the government's control, when needed, to be used either as fast cruisers or for transport service. New coast defences are being constructed and old ones strengthened. Although conscription has few or no advocates, still much care is taken to keep the army in effective condition both as to numbers and discipline, arms and other equipments. Though Englishmen are chronic grumblers, still, on the whole, they see no reason to doubt that their country is the best, bravest, richest, most civilized and most powerful on the globe.....

AGRICULTURAL NEWS.

SATURDAY, August 24, 1889.

THE Argentine Republic has addressed a formal invitation to the United States Government to take part in the second International Cattle Show of the Argentine Agricultural Society to be held at Buenos Ayres next April, under the auspices of the Government. The show opens April 20, and closes May 11. Prizes of $2,500 each will be given for various essays on practical subjects connected with Argentine agriculture. Arrangements will be made for exhibiting the principal breeds of cattle, sheep and swine, and agricultural products and implements. The competition in live stock and machinery is to be international, while that in agricultural products is to be exclusively national..... It is estimated that the National Cordage Company, the prime mover in the Twine Trust, will have a surplus of 25,000 tons of binder twine to carry over. This is good news to farmers. Perhaps there will not be such a scarcity another year.....An English farmer not long since was prosecuted by the health authorities on the ground that his silo was a nuisance. The higher courts to which he appealed decided in his favor..... ... The total receipts of live stock at New York and Jersey City last week were 17,105 beeves, 83 milch cows, 6,000 calves, 46,290 sheep and lambs, and 31,636 hogs. The exports from this port were 4,280 beeves, 69 sheep, and 9,440 quarters of beef. From Boston 2,643 beeves and 4,535 quarters of beef. From Baltimore and Philadelphia 2,301 beeves and 1,860 quarters of beef. From Montreal 2,861 beeves and 3,575 sheep. Prime steers are now worth in this market about $1.50 per hundred pounds less than they were one year ago..... Secretary Woodward says a pair of oxen will be exhibited at the State Fair at Albany, which tip the scales at nearly four tons. The fruit and flower show will be on Friday and Saturday, and is expected to be very fine. A butter factory will be in operation on Monday, and the new Swedish butter extractor will be in operation during the week. The railroads have given very liberal rates, and a fine exhibition and large attendance is confidently anticipated.....Delaware has a law for the protection of peach orchards from the yellows. It is unlawful to keep growing any peach, almond, or nectarine tree infected with this disease.....At present, 34 States observe what is known as Arbor Day. Nebraska started the movement 17 years ago, and it has proved a source of great benefit to her.... The Le Conte Pear formerly supposed to be free from blight, is reported to be badly affected in Georgia and Texas..... Kalamazoo, Mich., expects to realize $1,000,000 for celery this year. The crop is grown mostly by Hollanders, and few have more than two or three acres each.....The Grangers of Colorado combined to purchase their binding twine, the past season, of a manufacturer who was not a member of the Twine Trust. The secretary of the State Grange says that the twine has given good satisfaction, being of excellent quality, and cost several hundred dollars less than it would have cost in the Denver market.....Several cows which had died very mysteriously at Jersey City, were found upon investigation to have been poisoned by refuse from some chemical works..... California wheat-growers are doing a wholesale business in wheat harvesting. They have harnessed the traction engine to the combined harvester, and one of them cutting a 40-foot swath, will harvest 80 acres per day, ready for market. The engine is a straw-burner, and is said to consume not more than 30 per cent. of the chaff blown out of the thrasher. The drive-wheels are eight feet high, and the other parts are proportionately large. The header of this mammoth outfit is jointed in the center, and has two reels and two sickles, so that it can accommodate itself to inequalities of the ground. The power is furnished by a 50-horse power boiler. The traction engine runs the header, while the separator is run by a small, separate engine. The traction engine is also used for plowing, and can draw six six-horse gang plows, day and night, thus doing the work of 72 horses. Another advantage the engine possesses over horses is that it eats nothing when idle. Is it possible for the small farmers of the East to successfully compete against such odds?..... The Society of American Florists has been in session at Buffalo during the week. The Massachusetts Horticultural Society invited the Society to hold its 1890 meeting in Boston, and the invitation was unanimously accepted. Robert Craig of Philadelphia read a paper entitled Elevating Our Business, in which he agreed that the specialist achieved the highest success. A resolution was adopted favoring Dr. F. M. Hexamer of New York for Commissioner of Agriculture and Horticulture for the World's Fair of 1892, and John Thorpe of Pearl River, N. Y. to represent floriculture. The Society also petitions Congress to establish a floral school. Why not? Then why not the poultry-men petition for a poultry school; the fruit-growers for a pomological school; the sheep-breeders for a school of instruction in sheep-husbandry, etc.? Why not?..... The Farmers' Alliance Exchange of Florida has taken steps toward making Jacksonville the home market for Florida cotton. It has for many years been marketed at Savannah, and other points. The first bale of short-staple upland ever auctioned at Jacksonville was sold Wednesday. The bale weighed 579 pounds, and the cotton was of fine quality. The bale was placed in a wagon and driven through the principal streets preceded by a band of music, after which it was sold for 17 cents per pound. The Clyde S eamship Line will bring it to New York free.....Axtell tried at Chicago on Wednesday to lower his record of 2:14¾. He failed to make as good time as his previous record, making the mile in 2:15¼.....The farmers of Warren, Hunterdon and Sussex Counties, N. J., had a reunion on Wednesday.....

FIVE HARVEST EXCURSIONS.

THE Burlington Route, C., B. & Q. R. R., will sell, on Tuesday, August 6th and 20th, September 10th and 24th, and October 8th, Harvest Excursion Tickets at *Half Rates* to points in the Farming Regions of the West, Southwest and Northwest. Limit 30 days. For circular giving details concerning Tickets, rates, time of trains, etc., and for descriptive land folder, call on your ticket agent, or address P. S. EUSTIS, Gen'l Pass. and Ticket Agent, Chicago, Ill.—*Adv.*

Crops & Markets.

SATURDAY, August 24, 1889.

THE WEATHER during the last week has been much more favorable for harvesting and thrashing, although it has been rather cool for corn. There have been some local rains, but these have been needed where they have been heaviest. The Northwest had begun to suffer from drought in some parts, and the rains were very welcome.

WHEAT is thrashing out better than was expected, although much of it is rather damp. The demand for wheat continues good for all the interior mills, consequently the receipts at commercial centers are light. Brazil has imposed a heavy duty on all flour imported into that country, but wheat comes in free. English capitalists have invested large sums of money in the erection of flour-mills on condition that flour should be subjected to the maximum duty. This law has just gone into effect. Wheat is admitted free, and several cargoes of over 100,000 bushels each have already been contracted for. This will be good for the grain markets, but bad for the mills which have been shipping flour to that market for many years. The Argentine Republic is also under the same conditions. The Portuguese Government has also imposed a heavy duty on all foreign grain, and before it can be received, it must be shown that the consignee intends mixing each bushel with two of native growth. Protection of home industries seems to be contagious.

CORN is improving, but will require considerable warm weather to mature a good crop. The receipts of old corn are considerably increased; prices have changed but little.

OATS and other grains have been dull, and but a moderate trade is reported. Oats are a heavy crop, and the price is not likely to rule very high. There is no demand for barley yet. Large quantities of Timothy seed are offered, and the price is likely to rule low.

CHEESE has developed a stronger tone, and the market is steady. At Utica, July cheese is reported about cleaned out. Sales were reported at eight to nine cents. Little Falls sold the bulk of the offerings at eight to 8¼ cents. The Northern markets ruled somewhat higher, ruling at 8½ cents, taken mostly by Montreal buyers.

BUTTER is dull at present, excepting for the best grades which are in demand at outside quotations.

HOPS, from present appearances, will fall much below what was expected. The yards in central and northern New York have suffered considerably from mildew and blight. It is estimated that the crop will be shortened from one-fifth to one-third. Picking is progressing rapidly, and some sales are reported at 21 to 25 cents, although some buyers have been endeavoring to contract for 15 cents. Several counties in Canada report great loss to the hop crop from rust and blight. Many yards are totally destroyed. Reports from Washington indicate a good yield on that coast. The acreage is said to be 33 per cent. greater than last year, and the yield is expected to be 10 per cent. less per acre, so that the aggregate yield will be greater. The hops are said to be of good quality.

FRUITS are in large supply in this market, but the best qualities sell readily at outside figures. Several car-loads of California fruit are sold daily at auction, consisting of Orange, Honey, Strawberry Cling and Late Crawford Peaches; Tokay, Muscat, Black Prince, and Rose of Peru Grapes; Bartlett Pears; Golden Drop and Gross Prunes, etc.

PEACHES are quite plentiful and show quite a range in prices. Some parts of New Jersey report the peach crop very badly injured, probably not over half a crop. Good apples are scarce and sell at good prices. Good pears and plums command outside quotations, but poor grades go very slowly. There is a demand for the best quality of grapes at high prices, but others are slow of sale.

MANY of the muskmelons offered are in poor condition, and go very slowly. Prime ones are in demand. More care should be exercised in packing all kinds of fruit. They should be carefully graded, as it does not pay to ship poor fruit to this market.

VEGETABLES are in a fairly good supply. Potatoes are a trifle lower; sweets are very plentiful, and the demand is not large. Cabbages are large and fine and prices continue low. Tomatoes are lower, and receipts are very heavy. Corn maintains a good price. Onions are far in excess of the demand. Lima Beans are lower.

POULTRY is becoming more plentiful, and, with the exception of turkeys and geese, is somewhat lower. It will pay better to ship poultry alive, putting them in coops as directed in previous issues of the R. N.-Y. Send nothing but fat ones, and don't think you can crowd in a few poor ones and get equally good prices. It will pay you better to bury them at home.

EGGS are advancing slowly in price. Strictly fresh eggs, and this does not mean eggs that have been held for several weeks, will bring outside quotations.

HAY is in fair supply, and prices for a prime article are well maintained. The quotations are for old hay; new is selling for 55 cents to 85 cents.

A TRAVELER'S NOTES.

Regretable diversity in methods of farming among neighbors; the sharks swallowing the minnows in other vocations; is the same to be the rule in farming? Are bonanza farms and farming syndicates and trusts to supersede small farms? Certain alleged advantages of such a revolution.

While traveling through one of the best farming sections of America it occurred to me that there is altogether too great a diversity in the methods adopted by adjoining farmers. For example, one farmer uses a harvesting machine; another the antique but largely-used reaper; while a third gets along very well with the old-fashioned cradle. Now, a smart man with a good, four-horse team and a binder could do twice as much work as the three combined. In gathering hay I noticed the same thing. One farmer used a Eureka Mower, another a Buckeye and a third was struggling with a scythe. Neither of the mowing machines was in good working order. A good workman with a good team, with a Eureka or broad-cut Buckeye, could do more work than the three combined. Each farmer struggles along with old-fashioned machines or implements, usually in very bad order, because he needs them only for a few days. It does seem hard for a farmer to carry, say, $500 worth of haying and harvesting tools eleven months in the year when he only needs them for one month, or it may be for only a few days. Are not this diversity of method and want of co-operation among the principal reasons why "farmin' don't pay?" All other industries are managed on the co-operative plan. The small shops have long since been swallowed up by mammoth establishments. The smaller manufacturers and merchants are swallowed up by the larger ones, and the larger ones are in turn controlled by a trust. It is evident that this process increases the profits of the few, and in some cases it is a benefit to the smaller merchant or manufacturer who is employed at a good salary by the combination or trust. However much we may deplore the loss of individuality and personal independence, we must admit that trusts and combinations decrease the cost of production and increase the profits of the producers. These combinations, with the aid of improved machinery, are enabled to produce very much more than formerly with far less manual labor. This increases the profits of the producer, but lessens the demand for labor and injures the market for the farmer's produce by decreasing the number of consumers.

The only thing for the farmers to do is to combine. The stock and fixtures required to work 10 farms of 100 acres each, would proportionately cost three or four times as much as the stock and fixtures of a farm of 1,000 acres. By the use of traction engines, and thrashers, sulky plows, harvesters, and other improved inplements, an enormous saving in labor and cost of production is effected. The land in the East is divided into small farms and it would no doubt be better to keep them as they are if it were possible: but it is a question whether the competition from the large farms of the West is not becoming too great to permit the owner of small farms to make a living on them. One way to overcome the intense competition and reduce the cost of production, is for the owners, say, of a dozen or twenty farms to form a combination; throw down their division fences; make the fields very large, say, 100 acres in each; buy a traction engine, two or more harvesters, and a variety of other new implements; employ cheap foreign labor and the dividends which each farmer would receive would be vastly greater than his individual profits now are. I believe it is only a question of time when we shall see, instead of the thousands of small farms scattered over the country, a comparatively few large farms, and the owners of these farms will be thoroughly organized and able to command very much higher prices for their produce, than is possible under the present system.

H. P. S.

A VIEW OF TRUSTS.

ALL the signs of the times point to an early decadence of the system of trusts which have so unsettled the natural course of trade in this and other countries. This is only what might reasonably have been expected. The individuals composing them are so avaricious and unscrupulous that they do not hesitate at the extremest measures, and thus overreach all bounds, and hasten their own downfall. The Copper Trust exemplified this. Had it been content with moderate profits, it might still be exacting unjust and unnatural prices from those who were forced to use its goods. Another factor which enters largly into the general distrust of these combinations, especially among capitalists, is the nature of their association. To say nothing of the fact that their supposed capitalization is largely water, the method of combination makes investments in their securities very uncertain at the best. It is emphatically a trust; each rogue entering into the agreement must trust to the honesty of the other rogues not to rob him. From the peculiar manner in which they are associated, the individuals holding the stock of the concern are nothing more nor less than partners, as the trust has no legal existence, and is therefore not a corporation. They are, therefore, individually liable for any and all liabilities of the concern. This fact causes investors to hesitate about placing themselves in positions where they are liable to suffer the consequences of acts which they have no voice in controlling.

But the most potent factor in the overthrow of these iniquitous combinations rests with the people who are consumers of the products controlled. If they refuse to buy, or if their purchases be curtailed to a large degree, the sinews of war are taken from the enemy, and the length of time before its ultimate downfall is measured only by the surplus capital at command. Several trusts are now suffering from this condition of affairs. The Jute Bagging Trust tried to rob the cotton growers, but they rebelled and found other means of covering their crop. The Twine Trust endeavored to extort an unjust price from farmers for what they had come to consider a necessity, but every means was adopted to avoid its purchase, and it is now reported that the trust has a surplus of 25,000 tons of binding twine to carry over. The Sugar Trust also has a heavy load to carry. The demand for sugar from consumers has been very much smaller than ordinarily, and stocks of refined sugars have been constantly accumulating. Prices of raw sugars are tending downward, and the future supply is likely to be heavy. People in some instances are using raw sugar, thus leaving the refiners out of the account completely. It seems to be almost or quite impossible to secure legislation to control these combinations, but if the people who purchase their products refuse to buy, it is difficult to see how they can continue to exist for any considerable length of time.

MAGAZINE REVIEWS.

THERE ARE yet to be found, here and there in the world, some antiquated specimens of humanity who think, or pretend to think, that woman is an inferior creature; that she is mentally as well as physically the inferior of man; that she is out of place anywhere except as a house-keeper, wife and mother, which means in many cases, a slave to a man. Any one with such views should read The Home-Maker for August. Here we have a magazine for women, edited by women, its contributors nearly all women, and yet in the quality of its matter, in its arrangement, and in its general make-up, it will compare favorably with the best. "Cheap Living in Cities" by Catherine Owen, deals with economical methods of making various kinds of bread, which are of interest to many besides city-dwellers. "Cool Housekeeping for Hot Weather" has a refreshing sound, and the article gives many hints for accomplishing that desirable object. The vexed question of a Sunday dinner is very satisfactorily settled. A "symposium" on "Life Insurance" has been running for some months. It gives both sides of the question. Choice recipes for various dishes are given. There is a department for "Our Young People," "Our Baby," "Household Health," "Fashions," etc, The literary department is well filled. "The Twistifications of Molly Malloy" is a very clever dialect story. "In Wonderland, No. IV." deals with bees in California. "Another old New York Homestead" describes the Van Cortlandt Manor-House, and gives sketches of some of the distinguished people who have graced its spacious halls since its erection in 1681 on the banks of the Croton River. "In the Wilderness" tells how a city couple forced to find a quiet place to rest and recuperate, made a barren chamber in a farm-house into a veritable "cosy corner" at very slight expense. A feature of this magazine which pleases the busy reviewer is that its leaves are cut, so that he may plunge at once into its contents. Single number 20 cents. The Home-Maker Company, New York.

DRESS REFORM is coming to occupy a very prominent position in the feminine literature of the day. Magazines devoted especially to this subject are becoming more and more common. One of the most prominent of the reformers, possibly on account of her original and, according to some opinions, somewhat peculiar views, is Mrs. Annie Jenness Miller. The "leglettes" or divided skirts advocated by her, have given rise to a great deal of discussion. She conducts a magazine devoted to the dissemination of her views on the questions of healthful, convenient and appropriate garments for women, as well as to many other subjects closely associated with the physical well-being of the sex. This magazine is very appropriately called Dress. The July-August number, which is the first of volume III., contains a very valuable paper on "Physical Culture," relating to the important subjects of breathing and ventilation. Pure air is a necessity, and anything that hinders its free access to the apartments, or to every part of the lungs, is detrimental to health. Tight lacing is very injurious, and is a predisposing cause of pulmonary complaints. "Diet in Relation to Beauty and Health," is very ably discussed. "Poor Baby" is a very sensible article upon the proper treatment, both physical and mental, of that much-abused and long-suffering, but still ever-present member of society. There are "Fashions in Flowers," "Midsummer Fashions," "The Influence of Dress," and much other information which will be helpful to those who wish to dress healthfully, and yet fashionably. The frontispiece is a fine engraving of Mabel Jenness, one of the editors. Single numbers 40 cents. The Jenness-Miller Publishing Co., New York.

A VERY suggestive story which appears in the Pansy this month shows how true it is that "men are but children of a larger growth." Jamie Stuart gives his little sister "a piece of his mind" because she gave all her pennies to foreign missions, when it was so very plain that she ought to support home missions by buying peanuts of the grocer who had devoted all profits on the peanuts he sold for a time to buying a wheel-chair for a poor lame boy. The gentle little sister wanted to please him, so she bought two cents' worth of peanuts, and gave her other eight cents to the chair fund. But Jamie was still cross, for his interest in home missions all centered in the fact that Delia generally gave most of her peanuts to him. How many older ones have just about as deep-seated and real an interest in home missions as this. The two charming serials by Pansy and Margaret Sidney are continued, and another pretty and practical story is "Dimple's Dinner Party," to which, instead of inviting five little girls once, she invited one very poor little girl five times. D. Lothrop Company, Boston.

THE current number of The Writer is a woman's number, every signed article having been contributed by women. "Women in Journalism" by Mary Twombly, has some very good advice for aspiring women writers. "About Style," and "When to Write," also give very many helpful hints to young writers. There are several short articles dealing with different subjects of interest to authors; queries and answers, hints, etc. The Writer, Boston, Mass.

CATALOGUES, ETC., RECEIVED.

THE INDIANS.—The report of the Commissioner of Indian affairs for 1888 is sent by the Secretary of the Interior. What is to be done with our Indians? All who are interested in this problem will find "food for thought" in this ponderous volume. The commissioner, John H. Oberly, evidently believes that the Indian is capable of receiving our civilization. He quotes from Parton's Life of Jefferson the passage referring to the efforts made to civilize Indians at the William and Mary College nearly 100 years ago.

"Indians cannot receive our civilization. If the college had any success with an Indian youth, he was no sooner tamed than he sickened and died. The rest may have assumed the white man's habit while they lived at Williamsburgh, but the very day they rejoined their tribe they threw off their college clothes, resumed their old costumes and weapons, and ran whooping into the forest, irreclaimable savages."

Then Mr. Oberly goes on to try to show that matters are so different now, that the Indian cannot much longer resist civilization. It is to be hoped that this is so. Civilization implies work. There seems no good reason why the Government should support a lot of lazy Indians while the negroes at the South are obliged to support themselves by labor. The reports from the various Indian agents are quite interesting. The agents at Parker, Arizona, must have an interesting community to look after. Nearly all the Indians, he says dress in "citizen's dress" which consists of "an undershirt and a pair of overalls.' "These people know nothing of religion, all they are desirous of is something to eat when meal-time comes." It must be said, however, that many of the agents state that their Indians are becoming quiet, industrious and tractable, and ready to learn, realizing that their only hope for the future lies in civilization. All agree that if liquor could be kept from the Indians the task of civilizing them would be greatly helped. "Bad liquor and bad morals are twins."

After examining this report the R. N.-Y. is inclined to have faith in the future of the Indian. The writer has seen the lazy, worthless "redskins" of the West at their homes. There is little chance for them, but their children may make good citizens. Secretary Teller told the whole story when he said:—"The Indian question will never be settled until you make the Indian blister his hands. No people ever emerged from barbarism that did not emerge through labor." Let those who are to handle the Indians thoroughly understand that, and civilization for the Indian is possible.

GRASSES AND THEIR CULTIVATION.—This is the title of Bulletin No. 7 issued by P. H. Mell of the Alabama Experiment Station, Montgomery, Ala. There is little that is new in this bulletin. It is probably just as well that this is so as the bulletin is intended to interest and instruct a class of farmers who need a Primer before they can be expected to read in a First Reader. Here is one thought that the R. N.-Y. likes:

"There is a wide difference in the quantity of hay that should be fed to cattle. Some farmers give a fixed amount of all kinds of dried grass, hit or miss, in so far as the nutritive ingredients contained in the hay are concerned. Stock are thus sometimes scantily fed, because incorrectly cured hay may not contain enough food to satisfy them. In this day of scientific experimentation, the quantity of food measured to stock should be governed by the percentage of nutritive values the chemical analysis proves the food stuff to contain."

Is hay, hay? The R. N.-Y. has for a long time studied this question. It has been pretty well settled that milk is not milk, that cream is not cream, and that potatoes are not potatoes; that is, it is settled beyond dispute that one sample of milk or cream may be more useful in producing butter than another sample. Potatoes grown on dry, sandy soil may be of a very different flavor or texture from those grown on clay or naturally damp soils. Does the same thing hold true of hay? Take Timothy for example; are there certain soils, manures and climates so favorable to the growth of this plant that a ton of hay grown under these conditions will be more valuable for feeding than a ton grown under less favorable conditions? In other words—is hay, hay? This is a question the R. N.-Y. proposes to discuss. If there is any way of producing a superior quality of hay, we all want to know how it is done.

EXPERIMENTS IN PIG FEEDING.—Bulletin No. 19 of the Kentucky Station. Among the objects sought to be obtained by means of these experiments were the relative merits of shelled corn and corn meal, the value of corn-and-cob meal and the length of time that these foods could be profitably fed. As a result shelled corn is considered better for fattening than corn-meal, 63 days seem the limit of profitable fattening, and cotton-seed meal could not be profitably fed to pigs. The bulletin is not to be compared, for interest or attractiveness, with those on the same subject from New York, Kansas or Wisconsin.

THE EXPERIMENT STATIONS.—Miscellaneous Bulletin No. 1 from the Department of Agriculture gives the proceedings of the second annual convention of the association of agricultural colleges and experiment stations. Those who propose to keep track of the experiment stations will want to read this volume.

COTTON-SEED HULLS AND MEAL AS FOOD FOR LIVE STOCK.—The R. N.-Y. has called attention to the value of cotton-seed hulls in reviewing the bulletins of the Arkansas and the Texas Stations. The subject is continued in Bulletin No. 3 of the Tennessee Station. The station authorities have not conducted any feeding experiments of their own; they merely seek to bring to the attention of farmers a synopsis of what has been learned regarding the value of this food. Here we have a description of the hulls:

"The process of separating the kernels of the cotton seed from the hulls, in the oil mills, consists essentially in crushing and cutting the seeds and dividing the two portions by a system of screens and shakers. At first sight it would seem to be a physical impossibility for an animal to consume any appreciable quantity of the hulls thus produced. They consist of fragments of seed coats one-sixteenth to one-fourth inch in diameter, of dark brown color, very tough and leathery and entangled in a mass of cotton fibers, which still adhere to the outside of the hulls and which the ginning process fails to entirely remove. It is apparently the most dry and tasteless form of animal food which could be found. It is a matter of difficulty to reduce it to anything like a suitable form for analysis. In the mortar it forms an elastic felt, while it is scarcely amenable to any grinding process. Taken into the mouth, it is harsh and dry. Mastication promotes an abundant secretion of saliva as would be only natural with any similar material. It has very little taste and that apparently due to the small particles of the kernel remaining with the hulls. Altogether they possess apparently few inviting features as a food. In spite of this, it is said that animals which have never seen the hulls or meal before, soon acquire an eager appetite for them, and after a few days prefer such a diet to one composed of hay and corn. Probably this is due to the meal rather than the hulls which, as already noted, are well-nigh tasteless."

This is said concerning the effect of this food on the animal:

"From the large amount of fiber on the hulls the danger of bailing up or producing stoppages of the bowels might be anticipated. But we have been unable to learn of a single such case, nor is there even a tendency toward constipation. On the contrary, the effect upon the bowels is loosening which with an excess of meal may develop into "scouring." This is the well known result of excessive feeding of cotton-seed meal in connection with other materials. The hulls and meal seem to be particularly adapted therefore to being fed together, the effects of each counteracting the other."

The investigations conducted by the station indicate that the practice of feeding these hulls with meal as an exclusive diet is a sound one. The food produces a good quality of milk, beef or mutton, and also produces manure of a superior quality and texture.

These experiments are interesting and should be continued. While the R. N.-Y. believes that the most economical way of utilizing these hulls is in burning them for the ashes, it is still glad to see the matter pushed to a definite conclusion.

THE PARIS CONGRESS.—It appears that a "Congress of Agriculturists" was held at Paris last month. Farmers and others interested in agriculture were present from various countries. It was thought best to hold the meeting in connection with the great exposition where all products of the earth were assembled. The R. N.-Y. has received a partial report of the meeting. Most of the subjects discussed related to French agriculture almost entirely. A great deal of time was taken up in a discussion of methods for increasing the value of the grape industry. The Congress recommended offering a prize of $20,000 for the discovery of a Franco-American hybrid vine capable of resisting phylloxera, thriving in marly soils and yielding fruit of good quality."

One of the most thoughtful debates was that concerning the causes of the French crisis. France is a country of very small holdings or farms. Such a division is favorable to the production of grapes, poultry, dairy products and vegetables, but not for grain. The cheap wheat supplies from America, India, Russia and Africa, have a very marked effect upon French agriculture. After much debate the Congress proposed the following remedies for agricultural depression:

1. A judicious selection of seeds and manures, and the establishment of fields for demonstration and experiment. 2. The cultivation of cereals only in districts where they yield a profit. 3. To diminish, by co-operation the profits of middlemen. 4. Protection of each kind of agricultural produce by a duty on imports. 5. The abolition of internal duties. 6. A reduction in the charges of land transfer so as to encourage transactions in land.

As compared with the United States, France is a small and compact country. In discussing these recommendations this fact must be considered. As to the first point, few will deny the value of suitable seeds and manure. Many a farmer keeps himself poor, even in this country, by the use of varieties of plants that are not suited to his locality. Many use their manures so that part of the value is wasted. Those who use chemicals often lose half the money spent by injudicious selection of materials. The second point brings up an old matter for consideration. It is safe to say that in this country many bushels of wheat are grown at a loss, or at least, with no profit, though farmers think they get a certain value from wheat as a "seeding crop." What would be the effect upon our agriculture if wheat-growing should be given entirely to the States at the West where the soil is still strong enough and the farms still large enough to warrant the use of all needed machinery? Would Eastern farmers be better off? What crops could they substitute for wheat? Ten years ago these questions might have been asked concerning corn. The development of the silo, however, has changed that, and now, an acre of corn out of the "corn belt" can be made into silage with considerable profit. The R. N.-Y. is glad to see that even in France the people are disposed to investigate the profits of the middlemen. The "middleman" evidently is found everywhere. He should get his fair share of the money handled and no more.

Law.

"Every Man is presumed to know the Law. Nine-tenths of all Litigation arises from Ignorance of Law."

FIXTURES ON LAND.

L. S. M, Cedar County, Iowa.—What are "fixtures" on land? Several disputes have occurred of late in this neighborhood with regard to this matter, some insisting that certain kinds of property were "fixtures" and could not therefore be legally removed from a farm on the transfer of said farm to other parties: while others maintained that they were chattels and therefore legally removable. The RURAL'S answers to legal questions of general interest are so full and lucid, that by agreement, at least one dispute here has been left to its decision.

ANS.—As a rule, legally speaking, real property or real estate embraces not only land, but all improvements of a permanent character placed upon it. The term "land" includes not only the ground or soil, but everything attached to it, above or below, whether by the action of nature, as, trees, herbage, stones, mines and water; or by the hand of man, as, houses, fences, etc. In general, whatever the owner of a farm fastens to the ground or to a building, or uses constantly with it as an appurtenance to it, is a "fixture," and passes with the land. Whatever a hirer or tenant, however, buys or makes to use with the farm and fastens to the ground or building in such a way that he can remove it without injury to the object to which it is fastened, may be taken away Manure made from the products of the farm is a fixture, and passes with the land, or remains the property of the landlord on the removal of the tenant. In New Jersey, however, it is held to be personal property, and does not pass with the real estate as a part of it. In North Carolina a tenant may at any time before leaving a farm, in the absence of a covenant to the contrary, remove all the manure made on a farm. Manure made in a livery-stable or from products obtained away from the farm is personal property. A tenant has no right to remove shrubbery or flowers planted by him on a lawn or garden. In Massachusetts tenants are allowed to remove pig-sties, poultry-houses, green-houses and other fixed additions they may have made to the farm, provided their removal does not injure the property of the landlord. In all cases the tenant must remove all removable fixtures before the term of his lease expires, otherwise they revert immediately to the landlord.

Growing trees are fixtures of course; and if the owner of a farm should sell the standing timber and then sell the farm to a bona fide purchaser who has had no notice of the sale of the trees, the new owner of the farm is entitled to them, and the purchaser must look to the seller for damages. Trees that have been blown or cut down and have been left where they fell are "fixtures;" but not those that have been cut into lumber, logs or fuel. If a person should erect a building voluntarily on the land of another without any contract as to its final ownership, it becomes a part of the land, and he has no right to remove it. If, however, he erects the building upon the land of another with his consent, and upon agreement and understanding that he shall have the privilege of removing it, it remains his property. When a farm is sold, the grass or corn not cut and the potatoes not dug go with it. While ripe crops are in one sense considered real estate, however, in another sense they are not, for creditors may attach them as personal property and harvest them.

It is very hard to determine precisely what is a "fixture" and what a "chattel," and the courts in different States and sometimes even in the same State have decided differently in similar cases. Doors, windows, blinds and shutters, gas-pipes, cisterns, sinks and like improvements, put in by the landlord, are "fixtures;" but fire-frames, sinks, cisterns, gas fixtures and pipes and similar improvements, put in temporarily by a tenant, are chattels which can be removed if no injury is thereby done to the premises. As a rule, a tenant has also a right to remove pig-sties, poultry-houses, green-houses, and other similar buildings, erected for temporary purposes, provided he does not make or leave a cellar or other excavation. Where possible it would be safer to have a written agreement with the landlord with regard to such buildings. If a man leases land for a nursery, the young trees he sets out are personal property, and he may take them up and carry them away *before* he surrenders possession. A furnace in a cellar, even if it is a portable one, according to some decisions, goes with the land; but a kitchen range set up in the usual way, is personal property. Bean poles that have been used, whether stuck in the ground or lying in a heap, are "fixtures," but new poles are "chattels." The principle that underlies the numberless, sometimes apparently different decisions, is well stated as follows:

"Things personal in their nature, but fitted and prepared to be used as real estate and essential to its beneficial enjoyment, having been fixed to the realty or used with it, become part of the land and pass with it by the deed of conveyance, although they might be removed without substantial injury to the premises."

The above principles apply to mortgages as well as to sales of land, and to subsequent improvements as well as to those made before the mortgage was executed. In deeding land there is no occasion to mention fixed or permanent improvements, for doing so adds nothing to the value of the title. It is customary to do so, however, because most buyers feel safer if they have everything "in black and white," although such improvements, unless expressly reserved, go with the land, being considered part of it as a matter of course.

TESTING FERTILIZERS FOR WHEAT.

THE time has arrived when we must consider what fertilizer we will use on our wheat. If we have tried, in seasons past, different kinds and found one that gives satisfaction, we should use that again; but many farmers who use a drill for putting in their wheat and fertilizer, neglect to test the fertilizer by the simple plan of shutting it off in one or two places while drilling, so as to show exactly what the fertilizer does for the wheat and the succeeding grass and clover. Without this precaution, if the crop is a good one, all the credit is given to the fertilizer, and if it is a poor one it gets all the blame. No crop should be fertilized or manured without leaving a few rows or a small area unfertilized for comparison.

The engraving (see Figure 224) shows a part of one of my wheat fields where the fertilizer was shut off, the strip being just the width of the drill. The fertilizer used—raw and dissolved bone, equal weights, mixed and applied at the rate of 310 pounds per acre—in this case certainly paid well, as the crop without it would not have paid for the cutting; in fact, as nearly as I could judge, there were no sound grains at all in the unfertilized strip. This test surprised me very much, as I thought the condition of the soil was such as to give a fair crop of wheat without any fertilizer. The effect on the grass and clover is on a par with that on the wheat. A farmer, who has spent many thousands of dollars for fertilizers for wheat, was looking at this field and, of course, noticed the poor strip and asked what was the matter with it. I explained, and asked him if he did not always shut off the fertilizer at least once in drilling his wheat. He replied that he did not, but that he generally could see the effect of the fertilizer where the drill put it in unevenly. I thought that a poor way to test fertilizers, and have no doubt that he has lost the price of many tons of fertilizer by not adopting this simple expedient.

My other field of wheat followed a crop of cow-peas which were pastured and then plowed under. The same mixed fertilizer was used and, strange to say, it was very difficult to find the strips where no fertilizer had been applied they would not have been noticed at all were it not that on the unfertilized strips the heads of wheat stood up straight, while on the rest of the field they were inclined to hang down. This made a shade of difference in the color of the strips; the heads were the same in other respects. Now, if I had not tested the fertilizer I should have given it all the credit on both fields, whereas, in fact, the cow-peas should be credited with most of the good crop on one of them.

Moral: When you are putting in your wheat, spend 10 minutes in testing your fertilizer.

A. L. CROSBY.

Catonsville, Md.

Pomological.

A WALK AMONG THE PEARS.

MANNING'S ELIZABETH has a fair setting of fruit now ripe of about half the usual size.

CATHARINE: tree thrifty; crop moderate. One fatal fault of this variety is that the fruit is so hard to pick when ripe that the stems are broken off and it costs all the fruit is worth to pick it, as a rule.

BOUSSOCK was thought, a few years back, to be valuable. Now the fruit cracks and the tree is unproductive, though a fair grower. The leaves blight. One tree is enough to start with.

BARTLETT, the great pear, is the one to plant if one has but one tree. There has been more money in it for us than in any other we have tried.

BUFFUM: tree, a strong, upright grower, fruit too small. Not usually profitable, although productive.

SHELDON has never borne fruit here that held to the tree long enough to get ripe. This is its only fault: but it is a bad one.

CLAIRGEAU is a beautiful variety on the right soil; but it is not certain; the leaves drop when the tree is in wet or low ground.

OSWEGO is worthless here, though fine on some land.

DUCHESSE, fruit large; quality uncertain. Probably a large proportion of the blossoms do not get fertilized, as the stamens are too short. It is best on the quince.

ROSTIEZER is an amateur fruit; quality high.

WASHINGTON is of slow growth. The leaves are apt to drop. It wants rich land, and is suitable for an amateur.

KIRTLAND is usually hardy. The wet weather has been too much for it this year. The fruit is all cracked.

CLAPP'S FAVORITE is a profitable and good variety in every way except that the fruit must be picked early or it will rot at the core.

SECKEL, the standard of high quality, is generally hardy in all respects; but the leaves have been dropping badly this year. It is not profitable here. It will only pay where the fruit will attain the size of a Guinea egg. In all other sections one had better plant some other kind.

ANJOU, like the Bartlett, is the best of its season. In fact, I think Clapp's Favorite, Bartlett and Anjou are all worth planting for market in this section. It may be the Vicar ought to be included.

URBANISTE is nearly good enough to enter the list.

LOUISE BONNE DE JERSEY is almost good: the leaves are apt to fall too soon.

KEIFFER has been much talked about, condemned and praised. It is a good grower and heavy bearer and appears to be hardy. The

PHOTOGRAPH OF A WHEAT FIELD, SHOWING THE EFFECT OF FERTILIZERS. Fig. 224.

fruit is beautiful and sells well. It may be profitable, if people will keep on buying, at a good price, about as poor a pear for eating, cooking or canning as the country can furnish.

FLEMISH BEAUTY blights and cracks and is worthless.

D'ALENCON bears and keeps well. Indeed it usually keeps until March; but it is not very desirable.

DIEL blights in the leaf, and the fruit cracks: not valuable.

HOWELL can not compete with the Bartlett.

OSBAND'S SUMMER is a very good early pear, hardy in all respects.

PARSONAGE looks like the Bartlett. A slight astringency spoils this fruit for the table; but improves it for canning. I agree with the late Mr. Charles Downing that "this is a superior pear for canning." Hardy in all respects.

LUCRATIVE is a great bearer and very sweet; but it does not pay for market.

There was a prospect of a pear crop with us this year; but there are disappointments in pear-growing as well as in other pursuits. The earliest-blooming varieties set a fair crop of fruit; then we had several days of wet weather, and most of the blooms had passed the period of fertilization. The late blooms also set well, especially on the Vicar, and they are full enough yet, although fungus attacked the fruit when it was about the size of a pea, and wherever it struck, the pears turned black and dropped as also did the apples. This disease was especially destructive to the Greening Apple. There was a great set of apples and the weather was the finest when the trees were in bloom; but there isn't very much left except on the Smith's Cider, which promises to bear a good crop. No doubt this disease can be kept in check by spraying. Probably light showers may also help. That spraying the trees is beneficial, is, I think, established by experiment. I. J. BLACKWELL.

Mercer County, N. J.

Field Crops.

ALSIKE CLOVER

WHAT THEY THINK OF IT IN WESTERN NEW YORK.

COMPARED WITH TIMOTHY AND OTHER GRASSES.

FROM F. P. ROOT.

ALSIKE CLOVER has been quite extensively grown here in Western New York for many years past, and is, I think, growing in favor with the most progressive class of farmers; not that it is preferred to the common Medium Red Clover for fertilizing and renovating the soil; nor that it is preferred for pasturage or hay making; but it is liked because it is more sure to catch in seeding, and because it is the best substitute that we have yet found for Red Clover. It produces a fair amount of pasturage as well as a good addition to a hay crop, when sown with Timothy. During the past few years of extreme drought in the early part of the season, Red Clover sown on wheat, barley, or oats, has often failed of a catch and at the same time the Alsike has seldom failed; on the contrary, it has produced a fair return when common Red Clover has failed. As a renovator of exhausted soils I do not think it compares favorably with Red Clover. It has not the tap-root to penetrate the subsoil to bring to the surface the elements of plant food, and hence it does not gather nitrogen to feed the succeeding crops as the other clovers do, and yet as it is a leguminous plant, I look upon it as a better fertilizer, when plowed under, than Timothy or the other grasses commonly grown. The chief advantages in sowing Alsike, are its greater safety in seeding, and less liability to be winter-killed by the action of frosts, and also its staying in the land for a succession of years. It gives a crop of seed from the first growth and yields a larger crop per acre than other clovers, producing often seven or eight bushels per acre. It makes as good hay as the other varieties and is less liable to fall down, as it grows shorter and thicker on the ground. I have seldom sown it independently of other seed, but have mixed one bushel of Timothy seed, one of Medium Red Clover and half a bushel of Alsike. The last being a much smaller seed, will, with that mixture, produce more plants than the large clover when all grow and stand, and in droughty seasons will fairly seed the land when others fail.

In the spring of 1887 a field on my farm was seeded with the above mixture. The early season was very dry, (there being no rainfall from early in May till near the first of August). I regarded the seeding as nearly a failure, but of necessity it was mowed during the season of 1888, but a light crop of hay was harvested. In the season of 1889 it was mowed again, producing a good crop of excellent hay, Alsike Clover and Timothy, but no Red Clover could be seen in it. My soil is a dry, calcareous clay and clay loam, on which, in former years, the Red Clover grew abundantly and there were seldom any failures in seeding; but in later years failures, or at least partial failures, have been frequent, and it seems necessary to have something to fill the ground which would otherwise be but thinly seeded. So beneficial do I regard Alsike that I have not failed to mix in some of it with the usual quantity of Red Clover to be sown on my wheat fields. A full seeding of clover affords the surest guarantee of successful grain growing to the farmer.

Monroe County, N. Y.

FROM L. F. ALLEN.

I have cultivated Alsike for the past six or eight years, and esteem it more valuable than either of the Red Clovers for either hay or pasturage. It branches from near the root like a currant bush, with slender stems, grows a foot to 18 inches high on good soils. It bears a pink-colored flower full of seed in its first bloom, unlike the common red variety, which bears its seed only in its second growth after cutting for hay. Instead of a tap-root running deep in the soil, and apt to be drawn out by heavy frosts in winter and spring, it has a fibrous, spreading root, and stays in the ground for several years afterwards, not "running out" as the Red Clovers are apt to do. It makes a fragrant hay when properly cut and cured, and all classes of my stock prefer it to any other of the grasses. The flowers are among the best for honey-making, and bees seek it wherever they can find it. It blooms a few days later than the Red Clovers, and comports better with Timothy grass in season for haymaking. The seed is only about half the size of the red kinds, and but about half the quantity is required per acre. My rule of sowing is usually two quarts; while of the red kinds I use four quarts. Either of them, when laid down for hay, should be mixed with six to eight quarts of Timothy to the acre. For pasture I prefer it—as my cattle also do—to the Red Clovers. It is considerably grown in this vicinity, and largely grown in the Central New York counties; also to some extent in the adjoining province of Ontario, Canada. Its price at the seed stores ranges from six to eight dollars per bushel of 60 pounds, according to its yield in the previous year, in the succeeding spring markets. The soil where I grow it is a good clay loam. I do not know how it will thrive in a sandy or gravelly soil.

Niagara County, N. Y.

FROM HENRY IVES.

Alsike is better suited for sowing with Timothy, making a thick, fine bottom, ripening only a little earlier and the Timothy aiding to keep it upright, as it lodges badly when grown alone. The fact that its roots spread in the surface soil saves it from being killed by frosts on heavy lands. It will last many years in the land and it makes a better horse feed than Red Clover. It does well on all open soils from the flint hard-scrabble to the light muck, but not well on heavy clays. It is not sown to one-fourth the extent about here that the common early Red Clover is, for that is grown principally to improve our soil, for which purpose it is considered the best of all green crops.

Genesee County, N. Y.

POTATO NOTES.

THICK PLANTING OF POTATOES.

I HAVE been watching the RURAL'S reports about raising potatoes by the Trench System ever since it began to report, and last winter I noticed in one article that all the potatoes grew in the trenches—there were scarcely any between—and that set me to thinking whether it was necessary to have a wall of earth two feet thick between the rows. Why not have potatoes all through the soil? Then I thought that if we could have a row every foot, the tops would be so close together that they would smother the weeds and keep them down the same as wheat or oats do. So, finally, I concluded to try the plan and took a piece of sandy loam that had been manured the year before, and plowed and harrowed it as soon as it was in good order. Then I made a furrow near one side with the shovel-plow and dropped pieces of potatoes about every foot; then with the shovel-plow I made another furrow so close to the first as to cover the potatoes in the latter. Then I dropped pieces in the second furrow, and so on, till we got the plot planted. After the vines came up and were four or five inches high, with the garden rake I raked the ground down smoothly, and that was all that was done to the crop till we dug them when they were ripe. I dug a few and found out how they would yield, and then went to the village and got several witnesses to come to see some dug. We measured just one rod square and dug from it four bushels and something over a peck, making 680 bushels per acre.

I think that is pretty good, without using any manure and without any tending except the raking The potatoes kept the weeds down and the ground is clean. I saw a while ago a statement in the RURAL to the effect that a man, somewhere in the East, tried close planting, but I have not seen how he succeeded. I would like to hear from him.

I have also a piece of corn planted on the same plan, but can't tell yet how it will pan out. It looks nice and is clean without any work since it was planted, but I am a little afraid it is too thick to ear well. S. M.

Harlan, Indiana.

REPORTS ON R. N.-Y. NO. 2.

The sample tuber of the R. N.-Y. No. 2 potato was cut in 14 pieces, and planted in the garden. One piece did not sprout and one that sprouted was killed by a worm, so I had 12 left which grew nicely and gave me 12 pounds of nice potatoes, 45 tubers in all: nine under-sized, 36 of good size, the largest weighing nine ounces; one was rotten. J. C. E.

Bainbridge, Pa.

The Rural New-Yorker No. 2 potato sent me last fall, was planted May 7. On August 17, as the tops were dead, I dug the tubers. I made two hills, putting one-half the potatoes in each, and from those two hills I got four pounds and two ounces of smooth, handsome tubers entirely free from rot. There were 15 in all, only four of which would be called "small potatoes," and those four together weighed one-half pound. The largest of all weighed nine ounces, and the smallest a trifle over one. They were planted in quite wet land and in a piece near them the potatoes are rotting badly. J. W. C.

Southampton, Mass.

I planted the R. N.-Y. No. 2 potato about April 15th. The potato was the size of a hen's egg and had 10 eyes. I cut it into pieces of one eye each. These I planted in a poor, clay soil (without fertilizer) 12 inches apart, four inches deep in a trench, making one row 10 feet long. All the working they got was two hoeings. The last time I drew the earth slightly to them. The plants were a long time coming up, but grew very fast after they had started. They grew about three feet high, having purple blossoms and short-jointed stems. I dug them on August 16th and the yield was remarkable. There were 68 potatoes, which weighed 19½ pounds. They were almost all of one size. The largest weighed 10 ounces and there were but six smaller than a hen's egg. They are certainly a fine lot of potatoes and I am much pleased with them. Several who have seen them pronounce them very fine. G. R. W.

Lyndon, Ky.

Farm Economy.

POTATO PLOWS

How they Work in Various Soils.

Are they Ahead of the Potato Fork?

OTHER POTATO INFORMATION.

THE R. N.-Y. has had considerable to say in past seasons about the work of potato diggers Most of what was said referred to the expensive machines which are beyond the reach of the smaller growers. We now give notes from farmers who use "potato plows" of various designs. These tools are made and sold under different patents, though they all work on essentially the same principle. The potatoes are thrown out of the ground by means of a contrivance like two plows, one right and the other left, placed together so as to throw the earth in both directions. Above these plows are fastened long bars, The earth is to fall through the bars while the potatoes are supposed to roll off to the ground. In addition to giving their experience with the plows, our correspondents have been asked to tell us what varieties of potatoes are most popular with them, how the crop pays as compared with former seasons, and what can be done to make the business more profitable.

FROM JOHN DRESHER.

I have used and sold a potato digger manufactured at Hamilton, Ohio. The diggers have all been laid aside. The people prefer digging by hand. Among varieties the Ohio Junior and the New Queen are my choice for early potatoes; the Empire State and the Bell for late. We have had such dry seasons for the last two or three years that we didn't have much of a crop. The potatoes are mostly sold in Chicago in the fall of the year. It does not pay to raise them as well as formerly, the price is so low. We are having a large yield this year and expect the price to be low. I can't suggest anything to make the business more profitable, for when there is a large crop potatoes are low with us here.

St. Joseph County, Mich.

FROM H B. CLOTHIER.

I use the Knox Potato Digger manufactured at Gowanda, New York. I think it digs as clean as a man would ordinarily dig by hand, and it will dig from three to five acres according to the condition of the ground. I should think it costs to dig with this digger from one-half to two-thirds as much as by hand. For early potatoes I prefer Clarke's and Beauty of Hebron; for late sorts the Late Rose and White Star. I have also raised the Early Sunrise one year as an early potato and liked it very much. I think about 150 bushels is the average yield hereabouts. We sell them from the field when it is possible to get a fair price, as it saves handling. They are sold mostly to commission merchants in Bradford, Pennsylvania, and Buffalo, New York. I do not think the business is as profitable as formerly, because of extra expense for fertilizers and help, and also in keeping the crop free from bugs. I would suggest that machinery be used as much as possible. The ground should be well fitted and fertilized. I should plant with a planter and cultivate with horses.

Chatauqua County, N. Y.

FROM ISAAC K MORRIS.

I have not raised potatoes extensively—not more than from one to ten acres in any one year. I use the plow made at Hamilton. By harrowing the ground, I can get about all as clean as by hand digging. The plow is worked by two horses, and can throw the potatoes out as fast as the horses can walk. I would not exchange it for any machine I ever saw or used. I would not try to get along without it if I had but one acre of potatoes. I think the cost of digging is reduced from 50 to 75 per cent. The Burbank has been a favorite in our market—Cincinnati. The Early Rose has been profitable with me. The average yield is about 100 bushels per acre. We sell in Cincinnati or ship to other places. I do not see but what potato culture pays as well as formerly. My suggestion is to use plenty of fertilizers or manure in the ground where potatoes are planted.

Butler Co., Ohio.

FROM FRED. HARRIS.

I sent for a potato digger made somewhere East. It was so highly recommended that I thought I would try one; but it was not the one for our country. When our fall is wet and weeds and grass are heavy we use the mower to cut the growth, and rake it off. Then we can run our potato plow without clogging, throwing a wide furrow both ways, and as fast as a team can go. After picking up all in sight, we harrow, getting out all the crop as clean as by hand digging. We cannot get along without a plow. As compared with hand digging, plow digging is one-fifth better and it leaves the tubers in better condition for market. The variety mostly raised here is the Shaker Russet, but other varieties, such as the Peerless, Early Rose, Early Ohio, Mammoth Pearl, and Burbank are also grown. Our yield varies according to the season. Taking the seasons for a number of years, we average about 100 bushels to the acre. We usually sell in the fall in New Orleans and the South; but for the past two years our market has

not been what it was formerly, and we are not doing so well. Our Russet was the best field potato and the best yielder, but was not wanted in other markets. The dry weather early in the spring injured our crop to some extent, and too much rain after it came up was not much better. The crop will not be quite up to the average in our vicinity. Corn is doing well. Wheat is not quite as well as last year, having been injured by rust. Not much of it will weigh 60 pounds.

Ohio County, Indiana. F. H.

FROM M. C. NEWMAN.

I use a potato digger or plow manufactured at Rising Sun, Indiana. With careful hands to pick up the tubers and harrowing once, we can get them as clean as by hand digging. I have known 90 barrels headed up ready for shipment in half a day. A two-horse team and driver with four or five hands to pick them up will go over as much ground as a man and team will mark in a day. I don't intend to get along without the plow. I have never estimated the actual cost of digging by hand or with the plow; but I would put the cost of the latter's work at one-half that of the former, and when one wants his potatoes dug he can do so with the plow, and have done with the job. The most popular potatoes here are the Early Ohio and Early and Late Rose. An average yield is 100 bushels per acre. Most of the potatoes grown on the Ohio River bottoms are shipped to New Orleans; those grown in the interior, to Covington and Cincinnati at digging time. The crop pays as well now as formerly, where the grower can market it himself. I can only suggest to plant the best varieties on the best land with all the well rotted barn-yard manure one can give them, and to cultivate well.

Boone County, Ky.

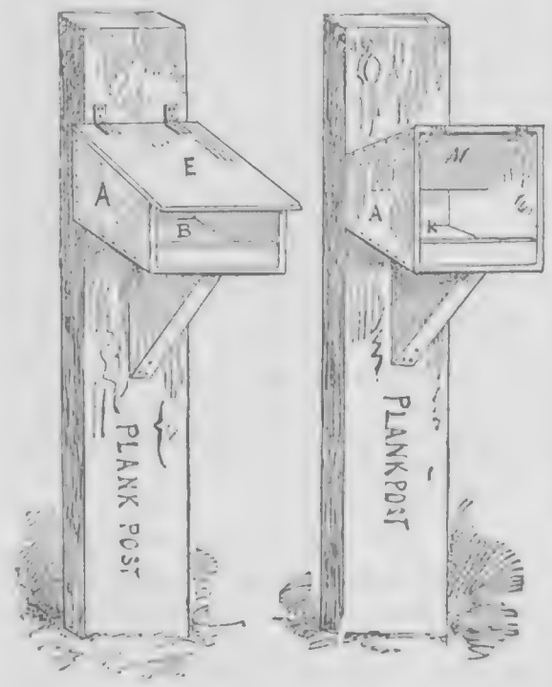
FROM D. S. SMITH.

I grow four to five acres of potatoes. I used the Common Sense Potato Digger one year. If the ground is clean and dry it does good work and saves labor. I can suggest no improvement except that for this soil it should be made of soft center steel and case-hardened like our best plows. For an early variety the Early Ohio, and for medium and late the Empire State are the most popular varieties hereabouts at present.

Greene County, Iowa.

SALT BOXES FOR FARM STOCK.

It is just as necessary for the thrift of farm animals that they should have salt, as that their food should be clean and wholesome; futhermore, the salt should be so placed that it may be obtained by them whenever nature craves it, and they should not be obliged to wait until the attendant deals it out to them, and as this is usually done it would be at irregular periods and in irregular quantities. It is to suggest a good means of properly "salting" stock that the designs of salt boxes shown at Fig. 227, are given. They are cheap



SALT BOXES. Fig. 227.

and simple affairs, but well adapted for the purpose intended. The object is to have a box holding a quart or more salt on the bottom, so arranged that when placed out-of-doors it will be accessible to stock and yet protected from rain.

The one at the left, Fig. 227, is nearly a foot square and eight inches deep at the back, and six inches in front, which is only partly inclosed. The lid E projects one inch in front. The whole arrangement is firmly attached to a post or building. The salt is placed at B in sight of the stock which soon learn to push up the hinged cover with their noses, and help themselves whenever they so desire. The one at the right is a little different, as the door is attached at the top, and is simply pressed against when salt is needed. It is best to fasten the door back as shown, for a few days until the animals know what the box contains, and then it can be allowed to swing in position. Any one using these or similar boxes will be surprised at the frequency with which stock visit them, and the sight will, I trust, educate the farmer to be more liberal with salt in the future. L. D. S.

Barrington, N. Y.

SKIPPING SEED PLANTERS.

T. H. HOSKINS, M. D.

GREAT ingenuity has been displayed in the invention of seed planters, and some of them seem to be, at least theoretically, perfect. Among these I have used in the garden the Planet Jr., and in the field the Eclipse for corn and beans, and the Aspinwall for potatoes. Going over the fields early in July, I was compelled to notice by far too many skips of seed or of fertilizer in both the horse machines. Where there was a long skip of fertilizer or seed, I am disposed to believe that in some, and perhaps in all cases, the fault was in the man rather than in the machine; that is, the man had neglected to fill the hoppers. But the man in charge was a careful one, besides being very handy and ingenious, understanding and working farm machines as well as any hand I have employed. The land planted (some 40 acres in all), was part fallow and part turned sod, all well plowed and worked fine with the Cutaway and Thomas Harrows. There were of course some broken sods; and the surface, in places, was somewhat stony; but, on the whole, much better than the average New England farm in both particulars.

I do not think that the Eclipse Planter ever fails to drop the seed regularly, and with a good degree of evenness, if the seed is free from sticks and dirt. All my seed was carefully hand-picked, and the "skips" were, strictly-speaking, not skips, but perhaps an even worse fault—the pushing along of the planted seed, making bare places with the seed bunched together at the end. This is caused by the coverer picking up a piece of soil, or a stone or stick, and pushing it along until the accumulating obstacles cause it to rise and go over. As said above, the land was much smoother and freer from these hindrances than the average.

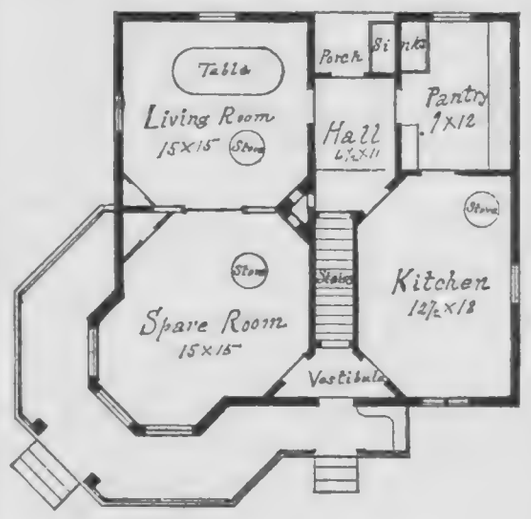
The fertilizer used was Stockbridge, the mechanical condition of which is certainly good; yet it was plainly to be seen along the bean rows where the full quantity was not distributed, the crop showing exactly the increase and decrease, with the absolute skips, where no fertilizer escaped. Now soft lumps are found in the best fertilizers. In a sample sent me from a new fertilizer factory at the copper mines in Capelton, Quebec, (where acid from the power copper ore is used in connection with apatite in making a very good and cheap superphosphate), the lumpiness frequently obstructed the machine, this being the only detect in the fertilizer, and one easily remedied. I mention this to show that the trouble with the fertilizer feed in the Eclipse Planter is that the pipe conveying the fertilizer becomes obstructed, when there are lumps in it.

As to the Aspinwall Planter, there are no signs of lack of uniformity in the distribution of the fertilizer, the color and growth of the crop being very uniform; but there are a great many skips, mostly short, but in all equaling at least 10 per cent of the whole field. That the fault is in the machine is proved by the fact that about a-quarter of the field was planted by hand, before I got the machine. The wheel that picks up the sets is a most ingenious affair, and I followed alongside, watching it for some time when it first started, without noticing a skip; yet the crop shows distinctly that some were made, and generally, when made, the skip indicated a succession of misses,—from two to 10 or more,—before it began to plant again. If this can be helped, this planter will do perfect work, and anyway I should use it. But I don't like the waste of fertilizer, running out without seed.

Architecture.

HOUSE FOR A FARMER.

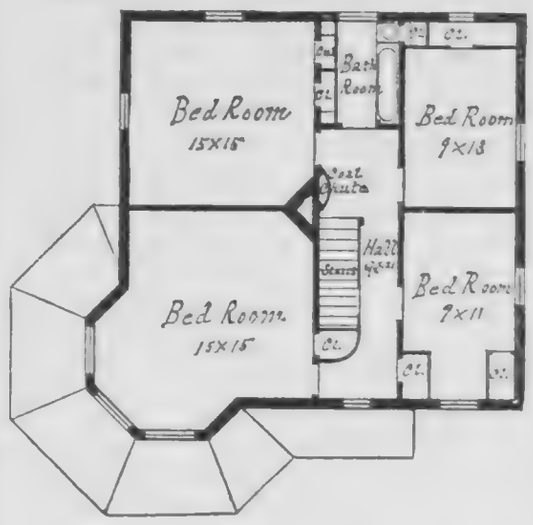
BECAUSE farmers do not often patronize architects, few of their building plans are really adapted to a farmer's needs. The building shown at Fig. 225 and 226 combines cheapness with beauty and the conveniences of modern life. As it is nearly square and has only one chimney and no expensive front hall and stairs it ought to be built almost anywhere, at from a $1,000 to $1,500, according to the finish. The kitchen and pantry are of good size; the back hall gives ample room for a farmer's necessary changes of coats, hats, etc.; while the porch and its sink afford a convenient place for men to wash and await meals without being in the women's way. By entering the cellar from the hall the expense and increased danger from frost of an outside cellar-way are saved. As shown by the dotted line, the ceiling of the hall next the kitchen is only seven feet in night, so as to permit the



LOWER FLOOR. Fig. 225.

kitchen stove-pipe to enter the chimney above it. The vestibule in front is large enough for a hat-rack and umbrella stand and is lighted by a glass door. The stair door might also have a circle of glass in it, and should open on top of the first step so as to indicate its character to a stranger. Where nut coal can be cheaply procured the chimney proper may commence seven feet six inches from the first floor and the coal be conducted by a chute from a bin in the attic into the base of the chimney, beneath the flue, where if the inner shell has openings, and the outer, small doors, it is always convenient for each stove The kitchen side of the house can generally be backed against a hill-side where a light, temporary bridge affords easy means of filling the bin.

Upstairs, Fig 226, all the bed-rooms have clos-



UPPER FLOOR. Fig. 226.

ets; there is one in the hall for extra bedding and the bath-room is convenient for towels, soap, etc. The attic stairs start about two feet from the floor. The hall, bath-room and two smaller bed-rooms are heated by registers in the kitchen ceiling. The family and spare bed-rooms have access to the chimney. If stoves are closed when not in use, the pipes from all may enter one flue. Two tanks or cisterns in the attic, filled by pipes placed in the angles of the double roof, can supply water for the bath-room. A pipe entering the chimney and returning to one of the tanks would give a choice of cold or warm water. The kitchen, hall, etc., of this house could be built first, and the more costly front portion could be added afterward. C. T. S.

Swanton, Md.

Dairy Husbandry.

DAIRY CONFERENCES IN CLINTON COUNTY, NEW YORK.

II.

Three conferences; number and kind of cows; their feed; treatment of the cream; handling and sale of butter; large quantities held back for future sale.

AT WEST BEEKMANTOWN.

THE conference at this place was held at the creamery of Mr. Thomas McGaulley, at which the milk from 400 cows and 60 patrons is daily made into butter. The cream was taken from the large vat into which it ran from the separator, after having ripened 27 hours, at a temperature of 60 degrees; the machine is a 25-inch Danish Weston, run at a speed of 2,700 revolutions. The cream was churned in a Blanchard 200-gallon box churn. The butter was washed in the churn, placed on a "Mason's Improved Center-drip" revolving worker, salted with Ashton salt at the rate of 1¼ ounce to the pound and packed in 62-pound packages. The cream was churned at 60 degrees; the temperature of the butter was 64 degrees. It was washed in the churn with water at 45 degrees. Pounds of milk creamed 6,682; pounds of butter produced 293½; ratio, one pound of butter to 22.76 pounds of milk. Quality very good. The cows are pastured on common upland pasture on which grow native grasses. No grain ration is fed. There is plenty of spring brook water in the pastures. The animals are salted at least once a week, and the milking is done at 5 A. M. and 6 P. M. The milk is delivered at the creamery only once a day—in the morning. The cream is ripened in a large vat at a temperature of 60 degrees regulated with ice, which is put into the cream, the work being done by the creamery man.

The afternoon churning was of cream from the herd of Mr E. A. Rea, of East Beekmantown; 267 pounds of milk were creamed in a Cooley Creamer. It was the product of six cows, one of which was a pure Jersey, two Jersey grades, a Holstein grade, and two natives. The milk was set 24 hours, at a temperature of 40 degrees. The cream ripened in 24 hours, at a temperature of 62 degrees to 64 degrees. It was churned in a Stoddard Churn at 60 degrees, by hand, at 60 revolutions per minute. Time of churning one hour. The butter was washed in the churn and worked on the creamery worker, salted with Syracuse salt one ounce to the pound. Product 11⅓ pounds; ratio, one of butter to 23 21 of milk. The cows have common upland native grass pasture, plenty of running water and they are salted every day. The butter is mostly sold in Plattsburgh, to private customers, at 23 cents per pound. The water used at this creamery is from a well, showing a temperature of 45 degrees; it is pumped into a large vat on the second story of the building, where is also located a steam-box where the butter packages are steamed, then soaked. The packages used are Welch tubs of ash and spruce, holding 62 pounds each. The butter is sold as fast as possible, mostly to hotels in the Adirondacks, at prices averaging 23 cents per pound, delivered on the trains.

The conference was held in the school-house, which was more than filled by an interested audience. Messrs. Gilbert and Curtis did the talking, or rather instructing. After the adjournment, an agricultural society to be called the "Plattsburg and Beekmantown Agricultural Society," was started by the appointment of a secretary and committee of five from each town. These are to meet and perfect the organization. It is hoped that much good will be the outcome of this conference.

AT MOOER'S.

At this creamery, which is one of Mr. Boomhower's, the milk is bought by him. At Saranac and Ellenburgh, and at the Peru cheese-factory it is made up for the patrons. There are 60 patrons and 450 cows. Three hundred packages containing 62 pounds of butter each, are in cold storage at the creamery. Very good butter is produced. The cream is raised by a 15-inch Danish Weston machine; ratio now one to 23: 7,200 pounds of milk are now received daily: maximum receipts 9,200 pounds. Average price for milk, 80 cents per 100 pounds. But one churning was done—the afternoon's. The cream was from the dairy of H. J. Hill, one of the patrons of the creamery; 184 pounds of milk from Monday night's and Tuesday morning's milkings were set in Fairlamb cans, in spring water at a temperature of 50 degrees. The milk was skimmed Wednesday morning, and on Wednesday evening the cream was mixed and left in a Fairlamb can, placed on the house piazza at a temperature of 65 degrees, where it was left to ripen till Thursday morning, when it was drawn four miles to the creamery, cooled down to 60 degrees, and churned in two churnings at 2 and 3 P. M. in a Stoddard Churn, driven by hand power. Temperature of cream 64 degrees, of butter 66; average time 23 minutes; product 8½ pounds of butter; ratio, one of butter to 21 64 pounds of milk. The herd consists of two Ayrshire and Short-horn crosses, one Holstein grade, and eight Short-horn grades. The cream was from the milk of the eight Short-horn grades only. The pasture is both low and upland, consisting of June Grass, Timothy and White Clover. The grain ration fed was eight quarts of wheat middlings in two feeds, per

cow, night and morning, with a small ration of hay. There was plenty of pure water in the pasture. Salt was given every other day, mixed with the grain ration. The churning was done by direction of Mr. Gilbert, and the butter was washed, salted and worked by him. A small audience assembled in an adjacent room and listened to instructions from Messrs. Curtis and Gilbert, and some remarks from Prof. Cooke, of the Vermont Experiment Station, which were very instructive and entertaining. The excellent "hay weather," and the desire of the farmers to improve it, were the causes for the small number of dairymen present.

AT ELLENBURGH CENTRE.

At this conference, held on Friday afternoon, the 19th, no churning was done. A late train delayed matters so that the instructors did not reach the creamery in time to do much. There was a good attendance, the large school-house hall being filled. The creamery is one of Mr. Boomhower's, and one of the best. Cream is raised by the Burrell & Whitman Ice-vat System, the vats having a capacity of 3,000 pounds each. The milk is from 86 patrons having 500 cows; 9,000 pounds are now daily delivered. Maximum receipts, 11,200 pounds; ratio at present one to 22.59. Milk is delivered twice a day. There are 500 packages, of 62 pounds each, of butter now in cold storage at the creamery. The milk is strained into the Burrell & Whitman ice-vats, and cooled to 46 degrees. It is skimmed after 24 hours' setting; the cream is allowed to ripen for 24 hours at a temperature of 60 degrees, and churned at 60 degrees in a 400 gallon Blanchard Box Churn. Some butter is sold to private customers and to the Adirondack hotels. The conference was a good one, and much attention was given by the audience. A nice dinner, spread in an upper room of the creamery building, and music by a brass band were two excellent features of the occasion. On the whole, the conferences were successful, and Clinton County may well be thankful for the quota which the State Dairy Association apportioned her. C. W. JENNINGS.

HOW THE GOVERNMENT CAN HELP THE BUTTER MAKERS.

J. W. NEWTON.

Good suggestions: work for the National Department of State through the U. S. consuls abroad; specimens of valuable information already given by them; need of a national association to battle effectually against "oleo."

There seems to be but one way to relieve the glutted condition of the butter market, and that is to export the surplus stock. This is being done to some extent, but not enough to cause any stiffening of prices. What is needed is a foreign market that will take large quantities of butter at a paying price, and afford a steady demand for good American butter. Now, why cannot the government, through the consuls, make an investigation of the various foreign markets and place the results before the farmers in consular reports? China has been suggested as a market for dairy products, and could a beginning be made it might lead to important results. The Department of State did a most excellent work in preparing and publishing the Report on Cattle and Dairy Farming. I find in that work many statements that bear on the subject we are considering. The Mexican consuls report as follows:

Chihuahua: "But little butter and cheese are made. Butter is worth 62½ cents per pound, and a very ordinary article of cheese 15 cents per pound." This is partly explained by the high duty.

Monterey: "Nearly all the butter used is oleomargarine imported from the United States, of a very inferior quality, which retails at 60 cents a pound in Monterey. In conclusion I would state that, if some enterprising dairyman would start the ball by bringing to market pure, rich milk and fresh, palatable butter, it would create a taste among the people for these luxuries, and a crying demand, before much time, for goodly quantities of both."

Tamaulipas; "Butter is not made to any extent.'

Our Consul in the Argentine Republic reports: "It may seem paradoxical, yet it is true that while the Argentine Republic contains about 12,000,000 horned cattle, it produces neither milk, butter, nor cheese... Such a thing as a dairy farm is unknown; such a thing as butter-making, in the true sense of the word, is a myth.....Butter, if it is used at all, has, until very recently, been brought from Italy. Of late years an unsalted butter, the work of Spanish Basques settled near Buenos Ayres, has been finding its way to market, but it is nothing more than coagulated cream, while the cheese comes mostly from England or Germany."

Brazil: "The fact that most of the butter used in a city like this (Rio de Janeiro) is the modern adulteration, imported in tin cans, is one of the many proofs that might be adduced of the backward condition of the dairy industry in this country."

These are samples of the reports from the countries south of the United State.

In Japan no butter or cheese is made. "There are no words in the Japanese language for beef, butter, and cheese, except these recently framed from the English for convenience sake, and in use only at the treaty ports. In China the consul at Canton says: "Butter is unknown in this part of China, except as imported from Europe and America for foreigners' use." The consul at Hankow could not "learn that butter or cheese is ever made, in this part of the Empire, at least."

It will thus be seen that there are millions of people who know little or nothing of butter and cheese, and it would seem that among some of them an outlet might be found for American dairy products. Oleo hangs like a dead weight upon the butter-makers of the United States, and there is good reason to believe that the exportation of oleo has had much to do with ruining the foreign market for American butter, which has existed in Europe. It would be well for the Department of State to ascertain how far this is the case, also the laws of different countries concerning adulterated and imitation goods, and also to learn how far these laws are enforced and what effect they have had upon the manufacture, sale, and consumption of such goods, and to publish such information for the use of American dairymen. It would be well, too, for Secretary Rusk to have the laws of the different States concerning oleo compiled and published, together with the United States law and the decisions of the courts in regard to the manufacture and sale of the stuff.

Another suggestion is that a National Dairymen's Association be formed. The State associations are doing most excellent work, but a national association is needed to fight oleo. It must be fought resolutely in every possible way. The government can aid the farmers in the ways I have indicated, and by seeing that the law is strictly enforced. We need a pamphlet showing the present legal status of oleo, to be used in the legislatures of the New England and other States; we need an association with a strong executive committee to push the battle wherever earnest work is needed, whether at Washington or in the State legislatures.

Stowe, Vt.

Farm Topics.

SOME COGITATIONS.

"Seems kind o' queer," lamented Mr. Bobcommon; "but I can't get hands to come and work for me like Cap. Jackson can. When his hay or grain is ready to harvest, or he is "rushed" with his corn, he drives into town and gets all the strong, young fellers he wants without any trouble. I offer the same wages and just as good feed, yet I have the hardest kind o' work to get any o' them stout young fellers to come out and help me. Can you tell me the reason for this?"

"Yes. Captain Jackson has two pretty daughters, and every summer he makes it a point to have two or three of their attractive city cousins or friends to come out and visit them, and rusticate with him. He has provided a nice croquet ground and lawn tennis lay-out, besides hammocks, swings, etc. The girls are always ready for a game after supper, and, bless you! the boys would almost work for the Captain for nothing to get to play with them. He has the pick of all the young fellows in the town, and every one that goes to work for him, I notice, takes a change of clean, light clothing along. At noon the girls are "not at home," and the boys eat, rest a short time and go to work. At night the Captain gives them time to bathe and trig themselves up a little before supper, and it is astonishing how clean and spruce they appear when they come in. The Captain is a jolly fellow and he's constantly poking fun at some of them during supper, after which he swings himself in a hammock while he watches them play. And don't they have a jolly time, though! Why I know young chaps who engage themselves to the Captain for harvest and haying nearly a year in advance. The old fellow is a schemer. His daughters and their friends do the greater part of the housework, almost without being aware of it, and at the same time give him advantages in the labor market that are not to be sneezed at."

A great light flashed upon Mr. Bobcommon's intellect and he walked off scratching his head with a whetstone and thinking at the rate of 40 miles an hour.

Some men who till the soil are constantly regarding themselves as martyrs to circumstances. They hate farming, but are obliged to stick to it to provide themselves and their families with food and clothing. They are always on the alert for a chance to quit "slaving," as they term it, and get at something else. Unobserved I sat down on a clod and waited for a plowman to return. He came trudging along with his head down, and I wondered whether he was watching for grubs or meditating on some important matter connected with his internal arrangements.

"Hello! Whoa! What were you thinking about so intently?"

"Why I was trying to make up my mind whether I'd better take Hank Jones's bet of $5 that the Chicago base ball club wouldn't win the pennant this year! They're a little behind now, but are playing pretty well, and I've a big notion to take him up. What do you think about it? How I wish I was as good a player as Anson You can bet your boots I'd not be here niggering!"

His wagons and other implements stood in a corner of the yard seasoning. His stable and—but we've all seen his surroundings.

On another farm I hid behind a hedge and awaited the return of another plowman. He was seated upon a sulky plow, held a tight rein and was looking at his horses and smiling complacently.

"Whoa! What were you grinning at?

"I was thinking what a fine stroke I made when I sold my hogs last Saturday. They dropped a cent Monday and are likely to stay down for some time. I had been watching the market closely for some weeks and nabbed it on the rise. If a man keeps his eyes open and strikes at the right moment he can astonish the natives every time. That lot had just reached their best point, and I made a good thing on them. I'll have another bunch ready in about six weeks—just in time to catch the market as it comes up again. Yes, this is my old clover field and the soil rolls up nicely. It averaged 27 bushels of wheat this year, and I ought to raise some splendid corn on it next. Like farming? Wouldn't trade it for any other business under the sun!" This is one of those farmers who are not looking about for a good "opening."

I passed a pasture in which were two groups, one of colts and another of cattle, huddled together the better to keep off flies. The field was as bare as a board and both of these groups were sizzling under the boiling sun. Some men say that it does no harm to horses and cattle to let them take the fierce glare of the sun through the long summer days. A mile farther on is another pasture with a small grove in one corner. All the animals in this one are gathered in the little grove and apparently enjoying the umbrageous shelter quite as much as human beings might, thus proving the advocates of shelterless pastures to be humbugs and base deceivers. I still think that the catalpa is one of the best trees in the world for pasture groves. Its growth is rapid, and its broad leaves make a shade so dense that neither weeds nor brush can exist beneath it. Another important point in its favor is the fact that no stock will eat it—at least no stock that I ever saw would. Both cattle and horses love to tear down and devour ash and Soft Maple, but they have no appetite for catalpa. Plant a little grove of catalpas about the center of your farm, so that the pasture will abut upon it when changed from one field to another. Place the trees about 4x6 feet apart, cultivate like corn a couple of years, and after that the trees will take care of themselves. With a few rods of movable fence, you can connect the grove with the pasture in a jiffy, and your flocks and herds will peacefully lie down therein and call you blessed.

Christian County, Ill. FRED GRUNDY.

Everywhere.

RURAL SPECIAL REPORTS.

Colorado.

GREELEY, Weld County, August 21.—There is really no such thing as potato rot in this part of the State. The crop will be cut a little short for want of water, but at least four-fifths of an average crop is expected.

C. F. M.

Connecticut.

FRANKLIN, New London County, August 15.—Potatoes are rotting very badly. Some farmers report an almost total failure. But few have been dug yet, but judging from the reports of farmers in this vicinity, I think there will be *less* than half an average crop.

G. H. G.

Illinois.

ROCK ISLAND, Rock County, August 16.—The condition of the potato crop in this neighborhood is good; there is no rot except on very low ground. I think there will be more than an average crop. Potatoes are selling at 30 cents per bushel and not very ready sale at that. Quality good. H. D.

QUINCY, Adams County, August 20.—There was probably nearly an average crop of early potatoes grown in this vicinity this season. Very few late potatoes were planted. We had fight enough with the bugs over the early ones to satisfy us fully. The rot has appeared in this neighborhood, but to what extent the crop will be affected by it cannot now be estimated, as but a small part has yet been dug. O. H. P. A.

Iowa.

SIOUX CITY, Woodbury County, August 18.—I have heard of no rotting of potatoes anywhere in this county. Their quality is unsurpassed, but the quantity will not be up to the average on account of dry weather. Oats were somewhat shortened on that account, but corn now looks as if it would yield an average crop, though I was informed yesterday that much in the bottom was drying up. Potatoes here are only bringing from 20 to 30 cents per bushel. J. N. S.

Michigan.

WHITE PIGEON, St. Joseph County, August 20.—Potatoes hardly ever rot in this country. I have lived here 36 years and have never seen a field of potatoes affected with wet rot; for the land is too dry and sandy. There is some prairie land here, but it is not much used for potatoes. We have a dry rot, however, which is bad in some years. Before the present year we had three years of terribly dry weather. This year, except during a long, dry spell in the spring, we had rain enough up to the second week of July; since then we have had only a light shower and things are drying up. The weather is hot by day and cool by night. Last year was the worst the farmers have ever seen. It was the driest, being worse than the two before it. For the last three years thousands of bushels of corn have been shipped in and sold to the farmers, and last year a good deal of baled hay was shipped in, taking money away from the farmers. Potatoes have been a light crop for three years past. What with the potato beetles and dry weather and low prices the farmers got discouraged and did not plant more than half the usual area this spring. The crop looked first-rate this summer; the tops were the largest I have seen for several years and there is prospect of a large crop if we have rain enough. The tops look nice and green. Wheat, rye and oats were good this year. Corn will be a fair crop if we have no early frosts. A good many beans are planted. The R. N.-Y. No. 2 did not come up well, but I will try it again next year on a larger scale. I never could raise a large crop from small seeds. The kind that does the best for me is the Empire State, as it stands more dry weather than any other sort I have tried so far. I hope the RURAL will keep us well posted in regard to prices for potatoes. We have no home market unless we draw 20 miles to Elkhart. Potatoes are mostly sold to commission-men who ship them wherever they can find a market. Our best market is in Eastern Ohio or York State. I like the RURAL first-rate. I wish I could place it in the hands of every farmer in the United States. [Thank you. Eds.] T. T.

BENTON HARBOR, Berrien County, August 17.—I have heard of not more than one or two cases where there is any rotting of potatoes; the acreage is perhaps about four-fifths as large as usual. In some places on low land perhaps one-fourth have been drowned out by the spring rains. In our immediate neighborhood, where on high land, the crop will be a good deal better than an average, perhaps enough better to fully make up for the shortage. The lands here are principally sandy with sandy or gravelly subsoil and our tubers seldom suffer from rot. Up towards Hartford, that is, northeast of us 18 miles, the crop looks poor. I was up there last week and I saw only one piece of potatoes that would yield over 100 bushels per acre. Out in the direction of Royalton on the bottom lands, I hear a good proportion are drowned out—fully one-fourth to one-third. I lose about one acre out of eight, owing to the wet in June. The rest look very well; about 2½ acres promise a very heavy yield, the remainder a fair crop. Corn looks

poor, being fully two or three weeks late. Strawberries paid well. Blackberries and raspberries sold very low, leaving the grower, after paying expenses, from 10 cents to 25 cents per 16-quart case and in a few instances they did not pay expenses. As these are what most farmers here make their money on, the outlook is bad for this winter. We have now had three very poor seasons. For my part I expect to make but very little this year, but I can go into a machine shop for the winter and make up for the shortage a little, as I worked at that business before I began on the farm.

R. B.

SOUTH HAVEN, Van Buren County, August 18.—Potatoes are 85 to 90 per cent. of a crop. Some rot is reported on low ground caused by excessive rains. Bugs are not so bad as in some years. F. D. N.

Minnesota.

MENTOR, Polk County, Aug. 20.—To the young man who is striving to make a living, and build up a home in the Red River Valley, this country offers a good many inducements. As the Red Lake Indian Reservation is about to be thrown open to settlement, there will be considerable land that can be had free from the government. For those who would like more of the benefits and improvements of civilization, there are numerous opportunities to rent farms that are all plowed up and have good buildings, fences, etc.. The owner usually takes a fourth or a third of the crops, and the renter takes the remainder, and furnishes seed, tools, etc. It would probably be a quicker way of making a good home to rent for a while, as the immediate use of the land (from 160 to 300 acres) helps a man to make a living, and to pay for what he buys as he goes along. As a general thing, this country is a good one for raising wheat, oats, barley, potatoes or any other hardy produce, but for fruit and any tender vegetables, it is not a success. The best way of getting such is to buy them, if we have the money; if not, we generally do without. I came to this country with the idea of overcoming some of the disadvantages of the weather, but have not made much progress in the seven years of my residence. F. A. H.

MINNESOTA CITY, Winona County, August 20.—Potatoes are not rotting in this country. There will not be a half crop owing to their ripening prematurely on account of the dry weather. There never was a better prospect two months ago. Small grains are excellent. Corn is now doing finely and will be a very good crop if frosts hold off.

E. B. D.

FERGUS FALLS, Otter Tail County, August 19.—Potatoes around here are fair; there is very little rotting, and fewer potato bugs than in past years. Some damage has been done by centipedes and cut-worms. Farmers around here do not raise any more potatoes than enough for home consumption. N. N.

New York.

CENTER LISLE, Broome County, August 20.—The blight has ruined the potato crop in this section. The vines are all dead. Late-planted potatoes are hardly worth digging and those planted early were frozen in June and injured so that there will be from this class hardly a quarter of a crop. Those planted in May will be about half matured and are rotting. Upon the whole, we cannot expect more than one-fourth of a crop. C. M. L.

CANANDAGUA, Ontario County, August 18.—Late potatoes in this neighborhood are first-class; early potatoes are rotting somewhat, but there are no complaints that late ones are doing so. The vines look vigorous and good and there is a fair prospect of a large crop. In some parts too much wet drowned the crop at planting time. E. P. W.

AVOCA, Steuben County, August 19.—Early potatoes are rotting very badly in gardens—at least 50 per cent. are rotten. In the fields on low ground they have blighted, and are rotting badly; but on higher ground they are all right. We will have, I should think, if the weather is favorable for the next six weeks, 60 per cent. of an average crop. They have not blighted so much during the last week. Apples are a complete failure. C. H. E.

North Carolina.

S. WASHINGTON, Fender County, August 19—Since my last report, on June 25, we have had constant rains and almost all crops have been cut off fifty per cent. and farmers are looking blue now. No potato rot here yet. Melons all killed out by wet weather and all vine crops and all peaches are rotting badly, and will be almost a total loss. There are no apples. Hogs are dying with cholera in this section. The cotton crop is almost a total failure. Some farmers who bought guanos for cotton and who have no cotton to settle bills with, will be ruined. D. J. MC M.

Ohio.

XENIA, Greene County, August 20.—What does the RURAL know about winter oats? Will they do as well as our spring oats? [Your climate will prove too severe for them. EDS.] Our wheat crop is fair both in quality and quantity. I think the yield is about three-quarters of our average. Oats very fine. Potatoes, early planting, good. Rural No. 2 a failure. The beetles and dry weather were too much for it. Hay was good and harvested in good condition. We have had but very little rain for the last four weeks, consequently the corn crop must be light. We have no pasture to speak of at this time.

D. D. M.

Pennsylvania.

BROAD FORD, Fayette County, August 19.—All harvesting and haying are about done. There was a very good wheat crop—30 per cent. better than last year. The oats were the best since the war, and grass and hay were very nearly double an average. I think hay will average nearly three tons to the acre in this neighborhood. Corn is good on high, dry ground that was planted early and ridged up, but most of it could not be worked enough and will not be more than three-fourths of a crop. Potatoes are also very good where they were ridged up early; but they are badly rotted where the land was not ridged. Level culture was a sad failure here with both corn and potatoes. Theoretical farming does not always do the best if it does look nice in print, and agricultural writers should be quite sure they are absolutely right before they ridicule every one who does not follow their teaching. There is a fair crop of apples. Some plums, but very few peaches. B. R.

INDUSTRY, Beaver County, August 25.—There is an immense crop of hay this year mostly put up in good order. Wheat and oats are good. Corn is late, but may mature if frost stays off late. Potatoes give a good yield, but are rotting badly. Apples scarce. Peaches a failure. Small fruits from very poor to extra good according to location and variety. The Crescent and Kentucky Strawberries did well; so did the Snyder Blackberry. It is a heavy cropper of medium size and very good quality and sells well in the home market. The summer has been quite wet all the way through. E. E.

SARVERSVILLE, Butler County, August 19.—Crops in this and the adjoining counties, so far as I know, have been better than for many years. There is an abundance of hay, and notwithstanding the wet weather more than half of it has been put up in excellent order, though some was spoiled a little and some a good deal. The price is low, or rather we look for it to be so, for no new hay has been put on the market yet. Wheat was got up in good shape. Oats not all in yet. I fear much will be wasted—an excellent crop. Pastures have kept green and juicy all summer, consequently cattle and young horses and colts are in fine condition. This is a great place for Clydesdale horses, there being a great market for them. Fall colts sell at from $65 to $85 each; yearlings do not bring much more, and two-year-olds sell from $100 to $140; three-year-olds from $120 to $160. Corn looks reasonably well, but potatoes promise a poor yield on account of wet weather and blight.

M. N. G.

MARTINDALE, Lancaster County, August 20.—The condition of potatoes in our neighborhood is good. There is a slight appearance of rotting, but it is not serious. The crop is being dug. The weather is favorable and the yield is about an average, and perhaps better than last year's S. W. S.

Wisconsin.

FAYETTEVILLE, Walworth County, August 17.—We are having another very dry season. Hay is a fair average crop. Wheat very poor. Thrashermen report from four to 11 bushels per acre. Oats a fair crop. Barley less than the average. Corn the poorest crop I have ever seen at this time of the year; it can't possibly be half a crop unless frost holds off very late. A good many pieces will not yield the seed used to plant them. Almost every night is cold. Flea-beetles are going to ruin the potatoes. Tomatoes are rotting as soon as they begin to turn red. Everything looks discouraging for farmers. E. R. B.

WAUNAKEE, Dane County, August 17.—The Colorado beetles, early, or rather late frosts, and the present dry weather have hurt the yield of potatoes in this section; but the quality of the crop is better than it has been for years. There is no rot in this vicinity. We shall be likely to get two-thirds of an average yield. E. C. D.

THE FARMERS' CLUB.

ANSWERS TO CORRESPONDENTS

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see if it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

BUNCHES OR TUMORS ON A HEIFER'S LEG.

C. B., Chemung, N. Y.—About two years ago a sore was produced on one of the fore legs of my four-year-old cow by a bruise made by a knot in the stable floor. On the place a large tumor or bunch grew and discharged matter freely. After a while tumors appeared on other parts of the leg, broke and discharged a thick pus. Since then they have continued to come and are now on all four feet and on the breast. They are mostly in groups of four to seven and range from the size of a hickory nut to that of a hen's egg. Some that had been opened with a knife discharged bloody matter. After doing so some disappeared, but others took their places. The animal is in good flesh and health, fattens more readily than most other cattle and is quite frisky. What is the trouble?

ANSWERED BY DR. F. L. KILBORNE.

The bunches are probably constitutional with this heifer, and it may require a long course of internal treatment in connection with the local treatment to remove them. Or they may be of such a nature that they will resist ordinary treatment or disappear at one point only to reappear at another. The simplest course would be to fatten the heifer for the butcher. But if you desire to treat her, try the removal of the bunches either by dissecting them off and then thoroughly cauterizing the surface with a stick of nitrate of silver, or by tying a strong cord tightly around the neck of each, to be tightened daily until they slough off. If an open sore remains, cauterize with the nitrate of silver as advised above. Internally give one ounce each of bicarbonate of soda and Glauber salts twice daily for 10 days or two weeks. Then give Fowler's solution of arsenic for a week, beginning with one-ounce doses night and morning and gradually increasing the dose to two ounces by the end of the week. Watch the patient while giving the arsenic, and if indigestion or diarrhœa occur, stop the medicine. If found desirable, repeat the above course two or three times, alternating the salts with the arsenic.

BLOODY MILK FROM INFLAMMATION OF THE UDDER IN COWS.

J. H. W., Medina, Mich.—A few nights ago while milking one of my cows, I noticed that she seemed restless, and that the teats were unusually warm. The next morning she gave bloody milk from one teat, and only a small quantity at that, while the others were almost entirely dried up. One side of the udder was caked very hard; the other side not at all. She had been giving 12 quarts at a milking. The udder is inflamed to such a degree that she moves the hind legs with difficulty. Last night another cow came up with the same difficulty. I had another sick the same way last year. They have been giving milk several months; are from six to 12 years old; grade Short-horns, and deep milkers. Pasture, bottom land. Some say that "buckeyes," to which they have access, are the cause, but the nuts are scarcely half grown. I have done nothing for them except to give them salts and apply soft soap to the udders. What is the trouble?

ANS.—The inflammation is probably the result of injury. If due to feeding on any injurious plant or tree, the whole udder would probably be similarly affected. Your treatment has been good. If the cases become severe, aconite, in 25 drop doses, two or three times daily, may be added, and a belladonna ointment may be applied to the udder after bathing it with the hot water or the sott soap, rubbing or kneading it for 15 to 20 minutes each time. Also milk three or four times daily.

STIFLE LAMENESS IN A HORSE.—DISLOCATION OF THE PATELLA.

J. M. W., Eugene, Oregon.—About fifteen months ago, my three-year-old mare became suddenly lame in her left hind leg which appeared to be paralyzed. She would go along dragging the front of the hoof on the ground. The first time it occurred she remained lame for half a day; then was all right again. Since then she has been troubled three times in the same way, but these attacks were not so severe as the first. There is no swelling or any sign of injury to the leg.

ANS.—The periods of lameness in your mare are due to dislocation of the patella or knee-cap at the stifle, the relaxation of the ligaments allowing the bone to slip outward where it may be felt at the outer angle of the joint. When thus dislocated, the patella may sometimes be thrown into place by starting the horse under the whip, the sudden effort made to bring the limb forward jerking the bone into place. The safest method, however, is to draw the limb forward with a rope around the fetlock, and passed through a collar around the neck. While an assistant draws the limb forward with the rope, you press on the outside of the knee-cap with the hand, until it slips into position. An active blister applied over the whole joint will tend to strenghen the ligaments so that the bone cannot slip out of place.

SMALL FRUITS FOR MINNESOTA.

J. J. W., Walkerville, Mont.—Will you kindly inform me through your correspondents' column what are the best and hardiest market varieties of the following small fruits for Minnesota near St. Paul: strawberries, currants, gooseberries, blackberries; and will the canes stand the cold winters there without protection?

ANSWERED BY PROF. J. L. BUDD, AMES, IA.

All the leading varieties of the strawberry with good foliage do well near Minneapolis, with proper winter protection. The Crescent fertilized by the Countess is largely grown there by small fruit growers. Windsor Chief, May King, Jessie, Bubach, and many other good sorts have been favorably reported upon in that region. All the currants do well there. Probably Red Dutch, Victoria, Long-bunched Holland, White Grape and Fay take the lead with the larger growers. Of gooseberries Downing, Houghton, and American Seedling are favorably reported. Of blackberries Ancient Briton, Snyder, Stone's Hardy and the Windom Dewberry take the lead. In Iowa as well as in Minnesota it pays best to lay down the canes in the fall.

HOW TO GET RID OF COCKROACHES.

J. C., Great Kills, N. Y.—How can roaches be destroyed?

ANS.—A friend says he has completely rid his house of roaches by a conscientious use of California Buhach, and as his house was completely overrun by the creatures he considers it quite a test case. He purchased the fresh Buhach from a wholesale grocer, and every evening before going to bed puffed it with a small pair of bellows thoroughly through the rooms in which the roaches abounded, particularly in the kitchen and pantries. He pursued this course every night for a week, after which a cockroach was a very rare thing. Every one who has tried this method fairly, reports the same result. There are other methods, but this is so completely satisfactory that they are not worth trial.

YOUNG PIGS DYING.

J. H. L., Emporium, Pa.—I have a sow that gave birth to eight pigs and seemed to do well, but did not eat for two days, and appeared lame. The pigs throve well, but now when a week old they are dying. They seem weak and scour. I have fed them on house slops with milk and chop. They appear hungry. The sow is in good flesh. What is the matter?

ANS.—The described condition of the young pigs may be due to any one of several causes, viz.—feverish milk, owing to disease of the sow; unwholesome or unsuitable food; a close, fowl pen; or to a specific disease, as hog cholera or swine-plague. Treatment of such cases is unsatisfactory. The condition is one to be prevented rather than treated.

Miscellaneous.

Several Subscribers.—The Occident Creamery, mentioned in a recent RURAL, is made by the Moseley & Pritchard Manufacturing Co., Clinton, Iowa.

V. L., Caledonia, N. Y.—A friend has an 11-month old Jersey heifer which has never had a bull, but she has a large bag full of milk.

ANS.—Our advice would be *not* to milk the heifer. By regular milking probably a considerable flow of milk could be developed; but

Miscellaneous Advertising.

"Herbrand" Fifth Wheel for Buggies.

with a heifer so young it would check her growth and development so as to impair her future usefulness.

M. P. C. Scranton, Pa.—Of the different varieties of asparagus planted in the Rural Grounds two years ago, which are the most desirable?

ANS.—For one reason or another, the plants started with vigorous growth unequally. This was probably due to the size and age of the roots, the way they were packed and had been kept, etc., etc. Another season will be required before we can make any serviceable report.

"Subscriber" Bluff Point, N. Y.—In competition for a prize for the best yield of potatoes on an acre would it be a "square deal" to raise a crop of early potatoes, and before digging them, plant another crop of late potatoes? It would all be on the same acre!

ANS.—It would depend upon the conditions of the offer. If the R. N.-Y. offered such a prize, it would consider that but one crop would be fair, and it would make this point one of the conditions.

F. A. C., Glendale, N. Y.—1. Will ashes soften bones so that they can be readily pulverized fine enough to be used as a fertilizer? 2. Are old bones that have laid out for several years as good as any? 3. Would it be advisable to take up and transplant runners from spring-set strawberry plants.

ANS.—1. Yes, but it takes a long time, and the method is deemed impracticable. 2. Yes, in so far as phosphoric acid is concerned. They lose some nitrogen. 3. Yes.

DISCUSSION.

HOTEL SWILL AS FOOD FOR SWINE.

HENRY STEWART, MACON COUNTY, N. C.—No doubt my friend Col. Curtis, who knows more about swine and a good many other things than most people, is right in his remarks about the unwholesomeness of hotel swill for feeding swine. But it is evident that the basis of his objections are not quite pertinent to the subject. Chemistry is not always to be depended upon, as when the New York Experiment Station, some years ago, referred to "putrid" brewers' grains as containing all the requisite elements for feeding dairy cows, and so gave rise to groundless objections to the use of this valuable food in a proper condition, that is when fresh and sweet, or preserved in silos as was the custom in the best dairy districts in New York State, long before silos for fodder were ever thought of in America. So the objections raised against hotel waste because it is sometimes fed improperly, are equally groundless, as also those raised against it when fed in excess. All kinds of food in a putrid state, or if given in excess, are detrimental, but it should go without saying that no kind of food should be used in this condition or to excess.

Moreover, the swine fed at the places referred to are not always kept in a healthful condition. I have seen them belly-deep in ordure and a sickening mass of decaying food and half-liquid mud. It is simply a case of using good food in a bad way. A farmer who could procure a supply of this valuable food containing bread, scraps of meat, vegetables, potato and apple parings with the waste soup all combined, and in a fresh, wholesome condition, would be able to make the very best meat, and if the pigs were provided—as all pigs should be—with dry, clean pens and allowed a run in a pasture lot, they would be in no danger from disease. It is not the food, but the wrong manner of using it that is to be objected to.

J. E. S., WEST CONCORD, N. H.—Since reading what has been said in the RURAL about feeding hotel swill to swine, I have been talking with some parties here who feed this product. This is what they say:

PINE GROVE FARM.

Swill for this farm is gathered in old lard or pork barrels set in a common express wagon. The hotel and saloon swill is taken between five and six o'clock, p. m. every day, and the street swill four times a week, in the forenoon. He pays $100 a year to one hotel, and the same to one saloon; for the street swill he pays nothing. All swill is fed uncooked and without grain to all kinds of swine, excepting those that are fattening; to these scalded corn-meal is given in addition to the swill. The surplus is stored in the swill-house, and none over two days old is fed in summer.

For a hog one year old or more a common barn shovelful of swill is considered enough for a feed with all the drink required: all that is eaten at once is fed twice a day, and on this feed superior exhibition animals are raised as well as hogs for pork. Hogs that have had nothing but swill are all ready for slaughter. Experience, says the owner, is indispensable to success in feeding swill and of the ordinary grain-fed hogs seven-tenths would die if full-fed on this waste. The pigs from sows used to it, are equal in growth to any grain-fed pigs and suffer no greater mortality The hogs are sometimes sick from eating this refuse. This is caused by the carelessness and and inexperience of the help in feeding. Fish and lobster refuse should always be removed from the swill, and all sour and moldy substances should be put into the compost heap. All sick animals are removed to new pens, supplied with fresh earth; their diet is restricted to water with a little green stuff. The pork is of prime quality and in active demand. The profits of this feeding depend on the location, the distance one is obliged to haul the swill and what has to be paid for it.

In the present case the owner thinks fully 50 per cent. is profit, besides the manure. The hotel and saloon each make from one and a half to two barrels a day. The swill saves all grain until fattening-off time, and the owner would quit the business if obliged to use grain. The herd is made up of thoroughbred Chester-Whites, Poland-Chinas, Small Yorkshires, and a breed styled the Hampshires, with excellent grades of each of the above strains. All his hogs show a surprising uniformity and superior development that are rarely seen, even in herds fed highly on grain. Cholera he regards as the result of over-feeding, filth and crowding, and he thinks that more swine are made sick or injured by overfeeding than by starving. In support of this opinion, he shows his herd of 150 swill-fed hogs with no sickness among them. All were quiet as I passed there at noon and the hogs were lying lazily about the yards. There was no rushing pellmell to the troughs and squealing like bedlam. Surely swill-feeding is a success here.

N. H. INSANE ASYLUM FARM.

Here the swill is collected from the main buildings twice each day—at 9 A. M. and 2 P. M.—and drawn to the barn in a plank cart. It is there thinned to a slop and fed to the hogs—all they will eat up clean. No grain except shorts is fed to brood sows when suckling. Corn-meal is fed to fattening animals. As the swill is fed fresh no storage room except the gathering cart is required. No attempt has been made to raise and fatten hogs on swill alone; the swill is considered perfectly safe as feed, and no more losses are experienced than would naturally be expected in a herd of 125 head of hogs confined in a barn cellar. Recently 16 two-year-olds that averaged, live weight, 465 pounds, were sold.

The profit of swill feeding is in utilizing what would otherwise be wasted, and in saving nearly all grain in making pork. The manager can make no approximate estimate of the cost of a pound of pork, or of the value of swill as compared with corn. He thinks that hogs would pay for their feed and care by their work on the manure pile and by their own droppings, even if the pork were worthless.

Last spring out of nearly 75 farrowed, only a few small pigs were lost, and these were fed on the ordinary swill, when weaned.

"THE SINGLE TAX."

A. C. C., FARMINGTON, MINN.—In Mr. Chamberlain's first article in regard to legislation needed concerning monopolies, he gave a brief review of "Henry George's plan." Doubtless Mr. C. intended to make a plain and true statement, but in fact he did neither. He says it consists of removing all tax from all other property of every sort and putting it all on land values in form of *rent* paid to the State."

This statement, together with the italicised word *rent*, would be apt to cause one to think that Henry George intended to have the State assume the function of a landlord and lease or rent the land to the user; for how else can you pay tax in the form of *rent?* But, in fact, Henry George's plan is to abolish all taxes except that on land values, irrespective of improvements.

This tax would be paid as now in the form of a *tax*. The justice of this method lies in the fact that economic rent (or that value that attaches itself to land on account of the growth of the community) belongs to the community; while personal property and improvements on land, being produced by the labor of an individual, belong to the indivdual. Thus the Henry George plan would not allow the community to take what belongs to the individual, nor allow the individual to take or retain what belongs to the community, or, in other words, to the State. So in reality, it would not be what Mr. C. says, but the opposite—raising public revenue by taking rent (economic rent) in the form of a tax. In the same article, Mr. C says, (the R. N.-Y saw fit to publish it in italics on another page(:

"The world does not owe every man a living.] It does, however, I think, owe him a fair and equal chance to earn one if he can and will." All "single-tax" men will agree with Mr. C. so far. That sentiment has the right ring in it—"fair and equal." But to Mr. C. it is simply a "glittering generality." Or does he see what justice is, but yield the point for fear of opposition? For see what follows in his article: "That is, it owes him the *possibility* (italics mine) of needed access to nature's materials and forces, etc." Now see: in the first place Mr. C. declares for an "*equal*" (italics mine) opportunity and then drops from the "sublime to the ridiculous"by making it only a possibility of needed access, etc. Wouldn't it have been fully as well, if he saw no way to guarantee an equal opportunity, to have crossed out that paragraph altogether? But there is a way. There is always a way to justice. Tax men in proportion to their opportunities for producing wealth—or, in other words, equalize opportunities by making the holder pay into a common fund a sum in proportion to the value of his opportunity. Mr. C. says, further, that "since property is the result of labor wisely expended on material, and since land is material, philosophy seems to show that property may rest in improved land."

Philosophy may "seem" to show, but it does not show it. What it shows is that property may rest in improvements of land. In fact, all property is an improvement of land, for all wealth is the result of labor on land; Mr. C. says history seems to show that individual ownership of land is the best incentive to human progress and to the highest and best civilization. But every-day observation shows that it produces an aristocracy that does no work, yet enjoys every comfort and luxury that labor works up from land; while labor that produces it all has barely enough to keep from starving; and is known as the "pauper labor of Europe."

Mr. C. lays down what he considers the just principles of taxation, and assumes them as granted. No! no! Mr. C., they are not just, neither are they granted. Over 60,000 men and women in these United States have signed a petition slip containing a single name and address, asking Congress to investigate the single-tax idea. No! no! not granted by any means; all over the world to some extent and in English-speaking countries in particular, is the single-tax idea being discussed; and earnest men and women are working for it with a religious zeal that distinguishes the lover of justice.

WHEAT EXPERIMENTS; SEEDLING APPLES, ETC.

J. D., FOSTER'S, OHIO.—According to promise, I write to the RURAL about my wheat experiment. The wheat was drilled on corn ground, and on account of wet weather the corn did not mature till very late. Then, just as I commenced to drill, a cyclone blew down the shocks and about 160 rods of fence, which put me back several days. It was about the fifth of October when I had finished. As soon as the ground froze hard enough to bear a wagon, I scattered about half a load of straw thinly over it as far as it would go, and along with it different kinds of manure. The wheat looked well early in the spring, but we had very dry weather until too late for the rain to be of any benefit to the wheat. All the early-sown wheat made a fair crop, but the late-sown is all a failure. Still the manured wheat was better than what was not manured, and the mulched was about as good as the manured. I finished plowing the ground on August 7th, and am going to drill about 200 pounds of fertilizer to the acre, sow wheat and grass this fall, and clover in the spring. I had about 11 acres of oat and wheat stubble, five of which were manured with stable manure, and the other six with fertilizer at the rate of about 175 pounds per acre. The fertilizer was a mixture of bone and tobacco stems ground, at the rate of 800 pounds of bone and 1,200 of tobacco stems to the ton. The wheat was drilled on September 18 and 19, and grass seed sown at the same time. It made a good crop, though as I have not thrashed it yet, I cannot give the yield per acre. The Timothy is very fine and promises a large crop for next harvest. I could see very little difference between the effects of the manure and those of the fertilizer. Soon after commencing to drill, I forgot to fill up the fertilizer box. The fertilizer ran out at the lower end of the field, so that the width of one drill was left without any fertilizer. The wheat on that strip was not half so good as that on either side of it, and I can yet point out the place by the difference in the Timothy. One of my neighbors is going to use ashes, mixed with acidulated bone from the Bowker Company's factory. Should there be an extra yield, I will let the RURAL know.

Several years ago, at the RURAL'S suggestion, I planted seeds from apples and pears. Five trees grew from the seeds of a Rambo Apple, only two of which survived the cold of a very cold winter shortly afterwards. One of the two is an early sweet apple; the other resembles the Maiden's Blush, but I think it is a better apple. It is just beginning to ripen now, and is loaded with fruit, so that I have had to prop the branches to keep them from breaking. The crop was very full last year also, but not quite so full as this; but the apples were much larger. The tree in growth resembles a Rambo. I showed it last spring to a man who had worked several years in a nursery. He pronounced it a Rambo.

ARTIFICIAL HEAT FOR CHICKS.

P. H. JACOBS, HAMMONTON, N. J.—The experience of "L.," given in the RURAL of August 24, in attempting to raise chickens by artificial heat, is rather discouraging; but the difficulty was due to the mistakes of "L.," and not to the system. He forgets that the domesticated fowl, unlike its wild progenitor, can do well without nuts or acorns, though in his case no harm was done. He attempted to raise chicks in winter with the *warmth under them*, (which he did not learn from the old hen,) by placing them on a loft, with a stove in the room below. The experience given shows that "L." verified what he has been warned against several times in the RURAL, but his letter will have the effect of cooling the ardor of those who may be favorably inclined to the artificial method. With facilities within my reach for observing the hatching and raising of thousands of broilers annually, I will state that artificial hatching is as safe and certain, (and more so when large numbers are considered) as the natural mode, but we place the warmth *over* the chicks and also keep the room warm as well. Had "L." given his chicks a warm room on the ground, with an opportunity to go out-of-doors on clear, nice days, with a warm, snug brooder at night, he would probably have succeeded. He fed them rabbit meat, and "still they died," so he says. Certainly, for very young chicks can endure but a limited feeding of meat. He thinks artificial incubation, "out of nature," and was so informed by those high in poultry *lore* (probably not in *experience*) and he noticed that the young chicks hovered over the register, which plainly indicated that they preferred to hover near the warmth, as they would have done in a brooder. To raise chicks properly let the heat be over them, and let it be high enough to prevent crowding. A young chick is really as naked as a young baby, and must be kept warm. Its food must not be too indigestible, or bowel disease will result. A novice may not succeed at first, but it is as easy to raise young chicks in brooders as it is to do most other things that are properly understood.

A TARIFF ON POTATOES.

C. C. W., GRAND BAY ALA.—Yes; give us a tariff on bananas. If protection is such a good thing, give us a plenty of it and then I hope the farmers all over the country will go in for a tariff on potatoes, and so prevent our markets from being glutted with the product of foreign "pauper labor" and assure to home producers a living price for their tubers. Of course, it will enhance the cost to every consumer by the amount of the import duty, but don't the consumers have to pay all tariff taxation anyhow?

R. N.-Y.—There is already an import duty of 15 cents per bushel on foreign potatoes. They can be grown so cheaply, however, in Canada, especially in Prince Edward's Island and the other maritime provinces, that even after the payment of this tax, they can compete successfully in our sea-board markets with the home-grown product in ordinary seasons, and be sold for less in seasons of scarcity and consequent high prices. In such seasons large imports of potatoes are made from Scotland, England, Ireland, and the European Continent, especially from Holland and Germany, and the cost of production is comparatively so small, and the ocean freight so low, that they find a profitable market here even after paying duty. When, a few years ago, the potato crop was unusually short, European potatoes were quoted in the Chicago market, and a few shipments were made even as far west as St. Louis. If the foreign crop be large this year, therefore, it is likely that any deficiency that may exist in the Eastern States will be supplied from Canada and Europe rather than from the Western States, and foreign imports are pretty sure to keep down the prices of the domestic product.

THE CRANDALL CURRANT.

FRANK FORD & SONS, RAVENNA OHIO.—In the editorial notice which appeared in the R. N.-Y. in reference to the Crandall Currant, the Editor says: "We do not see any reason for assuming that this is a hybrid." It is possible that it is not; but there are several reasons for our belief that there

are strong grounds for such an assumption. It is a seedling, (grown from seed of the currant the RURAL refers to, of very choice selection), and it is far more productive than any thing before known. Although to the casual observer the leaf is similar to that of its mother parent, it is not of the same shape, and partakes much of the texture as well as color of the English Red Currant. We have been unable to germinate any of the seeds from the Crandall as yet, and when the fruit is cooked they almost entirely disappear, showing that they are imperfect, indicating its hybrid character. All who have eaten of the Crandall, including the United States Pomologist H. E. Van Deman, say that it is more acid, larger and more productive than any of the varieties of Ribes aureum they have ever known. We do not say that it is a hybrid, but the above, together with the fact that the parent seed grew near Red Cherry Currants, are very strong "reasons for assuming that it is a hybrid."

R. N.-Y.—We noticed a difference between the leaves as stated, but not more than is liable to occur between any seedlings, as it seems to us. So far as quality is concerned, we could not tell one from the other eating the berries alternately of the Crandall and the variety alluded to as growing at the Rural Grounds.

BUTTER-MAKING.

W. E. R., DOVER, N. H.—The weather for the past few weeks has been bad for butter making. We use shallow pans, and have not been able to get all the cream, and have to churn oftener. When a creamer is used there may not be so much trouble in hot weather; but from what I can find out, I am in doubt as to which is the better way, all things considered. If the creamers are so much better than pans, as the makers claim, why is it that so many large butter-makers use pans? About a year ago, the RURAL gave the methods used by six large dairymen whose butter was sold in New York. I think every one of them used pans. Not long ago I had a talk with a man who has a Cooley Creamer, but who was not then using it. He could not tell me that he had obtained any more butter by means of the creamer; but he said he had secured more cream; but it was thinner than that raised in the pans. I took a can about the size of a Cooley can, and put it in an ice-chest of water the temperature of which I kept at 40 degrees. The can was not submerged or covered. The cream rose very slowly and I did not get as much as from pans. Can the RURAL or any of the readers give us any information on this subject? If, all things considered, the creamer is better than pans, I want one; but at present I am in doubt, and as I get more for my butter than many who use creamers get for theirs, I shall continue to use pans.

DOES THE WORLD OWE ALL AN OPPORTUNITY TO EARN A LIVING?

C. W. W., NORWALK, O.—I have seen, in one of Henry George's pamphlets, the statement that "the reason why the poor have so little is because the rich have so much." I never could believe this doctrine, and I think it as incendiary as it is untrue. I should be sorry to say it myself. The condition of things revealed in the RURAL's Eye-opener, page 535, is terrible. That people, able and anxious to work for their living, should be unable to find an opportunity to do so, and that in such numbers as to make profitable the establishment of bogus employment agencies to rob these unfortunates of the little they have, is a condition of things to which the people should not submit for a day without making it their main business to seek and apply an effective remedy. They should never rest until this condition of things has ceased to exist, and it prevails in the country as well as in the cities. That the world should deny a man an opportunity to earn his living, and then condemn him for idleness, and despise him for poverty, is every whit as bad as murder.

CHURNS AGAIN!

J. M. C., HOPKINTON, N. H.—In the R. N.-Y. of August 3, I replied to some objections of P. C., of Milford, N. H., against the Blanchard Churn on the score of its inadaptibility to the granulation of butter. P. C. now desires to know how to manage the cream that adheres to the floats and the inside of the cover. When thick cream is thinned down to a proper consistency, there will be no trouble about its adhering to the floats of any churn. Thick cream gathered from the open pan, whether large or small, is not fit in that condition for churning in any churn, whether it has floats or not. If one desires to have the butter come in a granular form or in such condition as to admit of proper washing for the removal of all objectionable substances, the cream should be about the consistency of that raised by the Cooley process, in order to perfect the granulation and prevent adhesion to the floats or other parts of the inside of the churn.

J. H. G., QUEENS COUNTY, L. I.—I recently took dinner at one of the best hotels in New England. The fruits were bananas and oranges. In sight of the dining tables were hills literally covered with blueberries and blackberries rotting on the bushes because they would not bring enough to pay for the picking. With blueberries at eight cents per quart and bananas at 15 cents per dozen, the hotel proprietor took the bananas. Is not this evidence of the onesidedness of the American system of "protection." The poor, miserable, pale-faced children who work in the factories are "protected" and their wages are presumably made higher by a tariff, while the money which, on the same principle, should go to the farmers' sons and daughters is sent to the slave owners of the tropics.

G. R. W., LYNDON, KY.—Prof. Maynard certainly has not the Eldorado Grape, which is one of Ricketts's Hybrids. The R. N.-Y. is right: it is as early as Moore's Diamond and its equal in flavor. The vine is a good, strong grower with healthy foliage. The fruit is of a yellowish, transparent color and of a rich, pleasant flavor. It suits my taste exactly. It should be grown by every one who likes a good grape.

What Others Say.

PITHS AND REMINDERS.

HOARD'S DAIRYMAN's advice to every dairyman in Wisconsin, Minnesota and Northern Iowa, where the corn crop is very backward, is to build a silo. Unless the frost holds off until well into the fall, it will be quite difficult to secure a crop of corn. The real practical question will be how to save the largest money value in the corn. A crop of soft, half-ripe corn is of no account to put in the crib and if carried along until it can be cut and husked, the frost will have destroyed more than half the feeding value of the stalks. Just as soon as the ears have reached the glazed period, it is at the top notch of combined value of stalk and ear for feed. Why not cut it then and put it in the silo and thus save all the feed value it has, and save the expense of husking.....

IF you have more of such food than you have cattle to consume it, slip out and buy a lot of thrifty yearling steers and heifers or thritty sheep and put them on that silage. The sheep will be ready for very fair mutton by spring. Good silage, Mr. Hoard says, is the finest feed in the world to make winter mutton. There are lots of turns that can be made to make late corn of some account and thus not lose your summer's work. But the first thing is to save the feed and put it where it can be made use of at any time, and the silo is the only safe plan.....

THERE must be more butter made in January and only half as much as now in June and July. The market taste is now for fresh, newly-made butter. Packed stock is not wanted. Why will people persist in laying down summer butter to sell four months hence, only to scatter poor butter all through the season?.....

THE NEW YORK TRIBUNE says that lard softened with kerosene until it will just flow in summer heat makes as good oil for mowers, etc., as that sold by dealers at 100 per cent. profit—much better than some of it.....

W. BRAZELTON tells in Hoard's Dairyman how he kills the horns on his calves. He says get a stick of caustic potash, then when the calf is, say, 10 days old, take it by both ears, stand straddle of it, then let an assistant have a little water, wet the place where the horn would come, then after wrapping a rag around one end of the caustic, rub the other end on the horn spot. It being wet will dissolve enough of the caustic to cause a dry scab to form. If thoroughly rubbed for, say, a minute, one operation is all-sufficient. Mr. Brazelton's calves six months old thus treated have not a sign of a horn.....

THE AMERICAN FARMER urges upon its farmer readers the importance of carrying a small life insurance policy. Thousands have died when their little farms were only half paid for, and in cases where the husband had his life insured the widow was enabled to lift the mortgage and retain the farm for herself and children. Otherwise she was left destitute and thrown upon the charities of a not too charitable world. It costs but a trifle to take out and maintain a small policy, say $1,000, and the husband and father who does not do so is sadly neglecting his duty to his family.....

For Seasickness
Use Horsford's Acid Phosphate.
DR. W. W. BLACKMAN, Brooklyn, N. Y., says: "I am very much pleased with it in seasickness. Several cases have been brought to my attention where it afforded prompt and entire relief."—*Adv.*

WORD FOR WORD.

——BREEDER'S GAZETTE: "For 40 years and more American molders of the races of swine have been breeding out the bristles, and it is much to their credit that this by-product of swine husbandry is no longer secured from their hogs in sufficient quantities to meet the trade demands. It does not pay to raise hogs for their bristles. In this instance at least it is not well to encourage 'home production."

——PHIL. WEEKLY PRESS: "Whatever may be said against the silage practice, this one point is a hard one to get over, the fact that the silo is a practical insurance against bad weather in the storing of crops. Hay, and fodder as well, must be made while the sun shines, but there is always an opportunity to put the crop into the silo."

——WHEN Mr. Adams put his clover into the silo he covered it with a layer, two and one-half feet in thickness, of freshly cut Prickly Comfrey. This covering, weighing when put in over two and a half tons, subsequently settled down five feet with the clover, and until the layer of comfrey itself was only eight inches in thickness. Mr. Adams is quite pleased with the success of his experiment and says that a recent examination of the silo discloses the fact that clover is in a perfect state of preservation up to the covering, there not being a particle of mold even where the clover came in contact with the comfrey. The broad leaves of the comfrey in wilting became so compact and are so thoroughly interlaced and woven together that it would seem to make a most excellent covering for silos. Of course, this is but a single trial and must not be accepted as conclusive, but the fact so far as we have been able to go seems to indicate that the future covering for silos should consist of some green material instead of a light and porous protection."

——KANSAS CITY LIVE-STOCK INDICATOR: "Prof. Sanborn has been endeavoring for several years to secure justice for the Missouri Agricultural College, and because of his efforts in that direction, he has been set upon by those interested and made to appear as the guilty party."

——PUCK: "The dogs we are warned to look out for always seem big enough and ugly enough to look out for themselves."

"WHEN a woman is unsuccessful in scaring a hen out of the garden, it is probably because her shoes are only half-souled."

"HEALTH makes wealth—and there is more demand for the finished article than the raw material."

——LONDON GARDEN: "There are about 5,000 roses planted in beds in the garden of the Trocadero, at the Paris Exposition. The summer being hot, few flowers appeared.

——N. Y. HERALD: "Flowers express the tenderest emotions of the heart, a generous pity for suffering. They are the eloquent messengers of faith, love and hope.

The man who has butchered his wife in cold blood and is condemned to die therefore is not a fit subject for such gifts.

Crime should be faced with the frown of a righteous indignation. To send the murderer a wreath of roses indicates a maudlin sentiment and total misapprehension of the true relation of things."

——HOARD'S DAIRYMAN: "For a test we once kept several cans of milk submerged in ice-water for 72 hours, and then made a good sweet cheese of it, the milk and cream having, seemingly, become emulsified in the cheese vat, as completely as when set. Hard cream raised through open setting, unless melted or strained, will not be incorporated in the cheese. But submerged cream, not having had access to air, does not go in clots."

——"IF we mistake not, it has been shown that the corn-stalks wasted in Missouri every year, would, if siloed, feed more cattle than the State contains. So the waste would go on, unless the silo comes in to arrest the destruction."

——DR. COLLIER: "None are to-day more hopeful than they who have thus far failed of financial success in the sorghum-sugar industry, and simply because none know so well as they that their failure resulted, not from any inevitable condition, but wholly from preventible causes which in many cases even ordinary foresight would have obviated."

——"THE cost of cultivation of the sorghum is practically identical with that of corn, but if a quarter more labor were given to it, the improved character of the crop would justify the additional expense. The grain of sorghum may be prepared for market or for feeding at an expense no greater than attends the cost of harvesting corn. The average of seven extended estimates as to the yield of sorghum, and one of these estimates included returns from 21 States, gives an average yield of 29½ bushels of seed per acre. We may, then, safely conclude that inasmuch as it pays to grow corn in this country for the seed alone, so too will the seed of sorghum pay all the expense in the cultivation and harvesting of the crop. Indeed, there is abundant testimony to prove that such is the case."

——MESSENGER OF PEACE: "A certain man named Smith came to a farmer named Jones, wishing to buy a pair of oxen, and said: 'Those red oxen of yours suit me, and I will give you $120 for them.' Jones replied: 'That is $30 more than they are worth.' Smith looked wonderstruck at this remark. The farmer said: 'I know the value of those oxen better than you do. One of them is a little 'breachy,' and the other one cannot bear the heat so well as some oxen, and yet there are many good qualities in them. But, all things considered, $90 are all they are worth, and you may have them for that price.' Smith gladly took the oxen and said to a man on his way home: 'It beats all what a difference there is in the religion of men. Now, there is old James Clark, my near neighbor; I have heard him make many a long prayer. If he had owned those beautiful oxen he would have asked me $130 or more for them, and he would have called them a great bargain at that, and he would not have said a word about one of them being inclined to be breachy, and the other not very tough in hot weather. I do not know anything about religion myself, but one thing I know as well as I know where the sun shines on a bright day, and that is, there is a mighty big difference between Jones's religion and Clark's religion.'"

Hood's Sarsaparilla 100 Doses One Dollar

Is Your Blood Pure? If not, if you have boils, pimples, "humors," or indications of scrofula or salt rheum, you should take Hood's Sarsaparilla, which is the best blood purifier known. It effects wonderful cures where other preparations utterly fail. Be sure to get Hood's.

NOTHING ON EARTH WILL MAKE HENS LAY LIKE SHERIDAN'S CONDITION POWDER
Highly concentrated. Dose small. In quantity costs less than one-tenth cent a day per hen. Prevents and cures all diseases. If you can't get it, we send by mail post-paid, One pack. 25c. Five $1. 2 1-4 lb. can $1.30; 5 cans $5. Express paid. Testimonials free. Send stamps or cash. Farmers' Poultry Guide (price 25c.) free with $1.00 orders or more. L. S. JOHNSON & CO., Boston, Mass.

ENSILAGE MACHINERY DEPOT.
A full and complete line, from the hand-machine up to the largest, of the **Smalley Cutters,** the **fastest cutting, strongest, most durable** and **best** ever built, including **Carriers,** both straight and angle, of any length required, and **Extras** and **Repairs** of all kinds, constantly on hand. Having the **exclusive** control and sale of these Cutters and all the appliances for the same, for all of the New England States and a large portion of the entire East, together with the right to sell in nearly all the Southern States, application for illustrated, descriptive and free pamphlet, showing **"why ensilage pays;"** and for free catalogue of both **Tread** and **Lever-powers, Threshers, Wood Saw-machines, Feed-mills** and **Fanning-mills,** should be made to the undersigned, proprietor of the old and reliable Empire Agricultural Works, over 30 years under the same management. **Agents wanted,** and **special prices given** for introducing in new localities. THE R. N.-Y. WOMEN'S POTATO CONTEST.

THE reports of those engaged in this contest must be received at this office on or before October 1st.

THE potato vines to which we applied the Bordeaux Mixture "blighted" as early as any others. We attribute the "blight," in *our* case, first, to the flea-beetle and, second, to the wet season which induced rot.

THE R. N.-Y., as usual, planted a hill or so of all the novelties in water and muskmelons. The melons were late in setting, owing doubtless to the wet weather, and up to this time few have ripened and those that have done so were of inferior quality. The R. N.-Y.'s experiments this season—and we have never been more pains-taking with the work—have been disappointing and unsatisfactory in one way or another.

THE R. N.-Y. sent out small tubers of the "No. 2" potato last spring. Some of our friends were displeased because the tubers were not larger. The R. N.-Y. did its best to send samples. On page 590 are some reports of the yields obtained from these little tubers. One man man got 19½ pounds from his sample. When you see the price at which the potato will be sold next year, you will see what he made by his attention to a "little thing."

"No crop should be fertilized or manured without leaving a few rows or a small area unfertilized for comparison."—A. L. CROSBY, first page.

ATTORNEY-GENERAL HOGG, of Texas, declares that any combination of farmers to prevent competition in the purchase of merchandise is a violation of the Anti-Trust Law lately passed in that State. The question arose with regard to the action of the Farmers' Alliance in boycotting jute-bagging, that body urging the planters of Texas and other Southern States to use cotton-bagging exclusively, so as to punish the jute-bagging syndicate for its extortion. The Alliance, however was fully aware of the scope of the law, and the members propose individually to fight the abomination. Few of them are likely to patronize ginners who buy any kind of bagging except what they want.

WHAT Jerseyman says, on page 602, about a walking record for horses is worth considering. The most valuable farm pace is a walk. The R. N.-Y. pointed out the fact, some weeks ago, that all the freight that passes over our great railroads must first be transported by horse power. Improvements in the speed of this horse work have not kept pace with the wonderful developments of railroad transportation. Draft horse breeding is now a regularly established business in this country. Before long there will be as much money invested in it as there is in the business of breeding trotters. The R. N.-Y. sees no reason why the draft stallion with the best walking record before a load, should not command attention proportionate to the trotting stallion that heads the list of speeders. There is something in this idea. Breeders of draft horses should start the record.

A FRENCH seed grower and dealer in produce writes to the R. N.-Y. as follows:

"As American apples sell very well in England, and the crop in France is very short this season, I would like to try them here and buy apples from American dealers. But I do not know any fruit merchants in your country, and I would be obliged to you if you could give me information about this trade and the addresses of the best shippers. At the same time, I would like to know where I could buy cider apples at the lowest prices, and the names of the principal merchants."

The R. N.-Y. has sent instructions and addresses, and it is to be hoped that the correspondence may lead to a new market for American apples. It is doubtful if there will be much of a surplus this year for export, but years of plenty are to follow, and we need all the markets that can be found.

PROF. BYRON D. HALSTED assumes, and perhaps correctly, that the rot in potatoes is due to a fungus. We have this to say about it: This year, as last, those vines died first which were first and most seriously attacked and injured by the flea beetle. We know of several fields about us that were not infested with the flea-beetle. There was no rot in these fields. The R. N.-Y. has tried about 50 different kinds of potatoes the past season, all growing within a few feet of one another. In every case, so far as our careful attention to the matter offers a guide, it would appear that those varieties which were most injured by the flea-beetle have rotted most; those which were the least harmed by the flea-beetle were injured least. Has Prof. Halsted considered the potato rot from this standpoint? The question we raise is whether the fungus is the cause of the rot or a consequence of the injury sustained by the vines in consequence of the perforated leaves and the continuous wet weather which gave very favorable conditions for the fungous growth. We are fairly confident that just precisely the same cause which killed the potato vines *this* season, aggravated by continuous rain, killed them last year.

A COMMISSIONER appointed by the legislature of Vermont to ascertain the acreage of abandoned farm lands in the State, reports that 200,000 acres formerly cultivated have been abandoned by the owners. As a rule, the abandoned farms are scattered in different parts of the State; but the Commissioner finds that many of them are so close together as to make colonization by communities possible, and he proposes that inducements should be offered to Swedes to become occupants of the deserted farms. The proposition meets with general approval, and next spring an attempt is to be made to establish an experimental colony of 50 Swedish families. Should this prove successful, the plan will be followed till all the abandoned tracts are once more occupied. In all parts of the State the people are drifting from the farms into the towns or to other parts of the country, chiefly the West. The deserted farm buildings and fences are fast falling into decay and the once cultivated fields are growing up in timber. Many farms can be bought for less than the "improvements" on them originally cost. Is it likely that where the hardy, frugal, industrious Vermonter failed to make a living, the hardy, frugal, industrious Swede will succeed?

"Agricultural writers should be quite sure they are right before they ridicule every one who does not follow their teaching."—B. R., page 593.

$25.

TWENTY-FIVE dollars are offered by the R. N.-Y. as follows: Fifteen dollars for the largest and best shaped R. N.-Y. No. 2; $10 for the second-best. Description and weight should be sent in before November next. Those only who may be entitled to one or the other of the above prizes, *as judged by their own reports*, will be asked to forward the specimens to this office.

CONSTITUTIONALITY OF THE DRESSED-MEAT LAWS.

ATTORNEY-GENERAL CLAPP of Minnesota, will make an appeal to the State Supreme Court from the decisions recently rendered by two Circuit Courts against the constitutionality of the "dressed meat" law. He maintains that the presentation of the cases did not fairly cover the points of the law. In both instance the cases were made up to suit the views and interests of the dressed meat syndicate, and were presented before courts of its own selection. The decisions were rendered upon application for a writ of habeas corpus, and, as is usual in such cases, the Judges decided off-hand, without hearing the arguments of counsel and without the mature deliberation required by the importance of the question involved. It is contended that a law against the sale of imported dressed meat for sanitary reasons, is just as much within the police powers of the State as laws against the sale of imported liquor or oleomargarine, and such laws have been repeatedly declared constitutional by the State and United States Courts. The constitutionality of the "dressed-meat" laws is a matter of great importance to the stock-growers not only of Minnesota and the other States in which similar laws have been passed; but also to those of several other States in which the passage of "anti-dressed meat" laws was defeated chiefly on the ground that such laws would be unconstitutional. Of course, it pays the wealthy dressed-meat syndicate to contest every case to the bitter end; and the State should support its own laws by carrying a test case to the court of last resort—the Supreme Court of the United States.

"I still think that the catalpa" (C. speciosa by preference. EDS.) *"is one of the best trees in the world for pasture groves. Its growth is rapid and its broad leaves make a shade so dense that neither weeds nor brush can exist beneath it. Stock will not eat it."*—F. GRUNDY, page 592.

A FARMERS' TRUST.

"THE Farmers' Federation of the Mississippi Valley," has called a convention of the "wheat-growers of the Mississippi Valley" to meet at St. Louis on October 23, for the purpose of forming a gigantic syndicate, or trust, for the purpose of putting and keeping up the prices of wheat, corn, cotton, cattle and other agricultural products. Meanwhile the promoters strongly urge the farmers of the Northwestern States and Territories to hold their wheat off the markets till after the meeting of the St. Louis convention, "unless such prices shall be offered as will justify a reasonable profit above the cost of production, or $1 per bushel." The "federation," it tells us, is a joint-stock company, with a capital stock of $20,000,000, only $5,000,000 of which can be put on the market and sold. Farmers and local shippers can obtain this stock at the rate of 10 cents on the dollar, and the "federation" will not begin active business until $2,000,000 out of the $5,000,000 have been taken up. Consignments of grain, cattle and other produce are to be made by farmers to salaried agents of the syndicate, who will charge the usual commissions, but the profits will be divided *pro rata* among the patrons. It proposes to make a reduction of 90 per cent. in the number of middlemen and thus save a vast sum annually in commissions. An equal proportion of the retail men are also to be "wiped out." The chief evils to be remedied are the unprofitable prices of cattle and wheat, due to glutting the markets and exorbitant charges in handling; the excessive number of middlemen of all sorts, who eat up the profits that should belong to the producers, and the extortionate charges of the owners of elevators and stock-yards. Lower rates of freight by rail and water will, it is expected, be also secured, and the welfare of the farmer be advanced by securing lower charges and better prices for all his products. A good deal can be learned and something can be hoped for from all such projects. In the present case, doubtless not the least forcible objection would be that a "federation" or "trust" with a membership of several millions, having a multiplicity of products and often conflicting interests must be a very unwieldy and unmanageable organization.

A SERIOUS MATTER.

THE ORANGE JUDD FARMER is asked by one of its readers why it gives so much attention to Northern Montana. We need not publish the reply made to the inquiry, further than to say it is essentially evasive and untrue. The reason why it is full of Montana advertisements and Montana glorification editorials, is that the company owning the paper is personally interested, in a pecuniary way, in the sale of Montana lands. It is true also that these *editorials* which are assumed by the reader to be a candid, unbiased record of the information gleaned by the editor as he travels about the Territory, and of the opinions formed in consequence of his careful and thorough investigations, are really *advertisements*, pure and simple, according to contracts entered into with certain Montana agencies.

If the Orange Judd Farmer were the only farm journal engaged in this bad business, we might not think it worth while to call public attention to it in this conspicuous way. As it is, we deem it our duty, and it would seem to be the duty of all journals that have the good of their readers at heart, to publish the fact that this Montana boom is instigated, in a great measure, by a syndicate of agricultural editors acting in concert with railroad officials. The R. N.-Y. knows nothing of Montana, having declined polite invitations, first, to join this little editorial visiting band which was, a year or so ago, so liberally treated by the Montana railroad officials, and, later, the proposition to become pecuniarily interested in the enterprise which promised "immense returns for a small outlay in money." It may be all that is claimed for it. Chinook may in a few years rival the most favored Eastern cities. Our view is that those editors who have invested money in such lands and who are praising everything appertaining to them with scarcely any qualification, while their readers are left in utter ignorance of the incentive, are prostituting their high calling to the level of the most unprincipled monopolies, trusts or other combinations conceived and carried on chiefly from motives of greed, with little, if any, consideration for the real welfare of those who, through this editorial puffery, are directly or indirectly induced to leave their present safe homes to endure the hardships and uncertainties of pioneer life.

"The R. N.-Y. No. 2 potato planted was the size of a hen's egg. I cut it into 10 pieces of one eye, each and planted in a poor soil without fertilizer, 12 inches apart. etc. The yield was remarkable. There were 68 potatoes which weighed 19½ pounds," etc.—See page 590.

BREVITIES.

RED apples are wanted by the fruit sellers in New York.

YOUNG Leghorn roosters are the greatest nuisances that a poultryman can have in his flock.

NEXT week one of our correspondents will gives some reasons for throwing stones at a horse!

IT seems that wood bending is a regular business and one in which there is less competition than any other wood industry.

NO person should ever drive a horse who does not know how to harness or unharness. The women folks are included in this.

THE development of the dressed beef industry has made it possible for farmers to obtain bones for fertilizing purposes in larger quantities than before the business started.

IF the sugar trust people do not behave themselves, there will be a big boom in bee keeping in this country. Farmers will fight the trust by supplying a share of their sweets in honey.

ONE of the lambs used in a feeding experiment at Cornell University died from the effects of a stone in its bladder. The R. N.-Y. feels confident that many of our domestic animals, horses more particularly, suffer from this trouble.

SOME of the farmers near the Rural Grounds "make work" in picking up potatoes. Some pick into bags and load the bags into the wagon. Others throw the tubers into the wagon and pick them over while unloading. The R. N.-Y. will have light boxes—just large enough to fit into the wagon box two abreast. These are easily handled and can be quickly emptied.

Miscellaneous.

CORRESPONDENTS' VIEWS.

THE PLAGUE OF WEEDS.—The alarmingly rapid increase of all noxious weeds, when allowed to grow unmolested, should be sufficient inducement for those interested to use every available means for their destruction, though it may seem practically impossible to effect this when we consider the little effort put forth in this direction by a large proportion of the farming public. However, there are honorable exceptions where the highways, fence-corners, yards and inclosures connected with many farms present a clean and neat appearance; but on neighboring farms perhaps can be seen weeds of nearly all varieties luxuriantly growing unmolested, their seeds allowed to ripen and to be scattered broadcast, to produce ten times the number of pests another year. During my daily drive to the post-office half a mile distant, on either side of the highway, after passing the limits of my own farm, can be seen weeds of the following varieties growing in profusion: milkweed, teasel, wild carrots, nettles, Canada Thistles, golden rod, burdock, mullein, catnip, ragweed, yellow dock, sweet clover, broad and narrow-leaved plantain. All these force themselves on one's attention while the highway laws make it the duty of the overseers to cut the pests at least twice during the season where the owners of the lands adjoining neglect to do so. But this duty is in many instances entirely neglected; the seeds are allowed to ripen and to be distributed by the passing carriage wheels during a period of muddy roads from one locality to another. It is evident that this feature of the highway law should be rigidly enforced. Indeed, the New York Central R. R Company, to its credit be it said, is doing more for the suppression of noxious weeds on its grounds than many others who should consider it a work of vital importance, are doing on theirs; for the road people for several years past have regularly cut them (where the line passes through my farm) at least twice during the season. Not only are these older and well known *standard* varieties slowly but surely gaining a permanent foot-hold in all parts of our land, but others with new names, and equally objectionable characters, are persistently making their way to the front, seeming to defy the efforts of the painstaking farmer to destroy them. One of the most notable, and one that causes much speculation and anxiety among the farmers of Western New York, is the new and alarmingly prolific weed-pest generally known by the name of "Long John," resembling somewhat the common "chick-weed," though growing taller with blossoms of a light yellow color. Many careful and thoroughly wide-awake farmers are surprised at finding it intruding itself in their wheat fields, meadows and pastures. I am creditably informed that neither butter nor cheese of a palatable flavor can be made from cows pastured where this pest abounds. Thus we are admonished of the direful results of allowing these troublesome strangers, together with those of older acquaintance, to find a resting place among us, and with united effort we can possibly keep them in subjection, if we cannot entirely eradicate them. IRVING D. COOK.

Genesee County, N. Y.

SETTING IRON FENCE POSTS.—Iron fence posts are objected to because they cannot be set as easily as wooden ones. They are liable to be pushed over by the stock, since they present a small surface to the earth to receive support, as compared with wooden posts. Manufacturers have devised various contrivances to overcome this, but the result has been that the post is made so expensive as to render it impracticable. The iron post has so many advantages that I endeavored to discover some cheap method of setting it which would likewise make it firm in the ground. A hole six or eight inches in diameter was bored the required depth. The post was set therein and the hole filled with small stones pounded in carefully; a very small quantity of earth was mixed with the stones to make them "compact" more readily. A wagon-load of these small stones, which may be taken from the field or the bed of the creek at this season, will fill a large number of holes. It is much better to have the posts provided with a knob or something of this kind at the lower end to prevent them from being drawn up easily. While I have not given this method a lengthy test, yet I feel it will continue satisfactory. Another objection urged against iron posts is their expensiveness. An instance occurs to me where a farmer bought a lot of second-hand gas-pipes at a low price. These were cut into proper lengths for posts and given a coat of paint. They made most excellent posts and will last twice as long as wooden ones. What we need is that some manufacturer should invent a practical iron post—something that is cheap and has the stability of wood together with that lightness and neatness which can be found only in the iron or steel post. R. L. D.

Green County, O.

WASTE LAND.—While spending a few weeks' vacation recently in Western New York, I could not help observing the large amount of valuable land that was actually nothing but weeds and briars, and yet many farmers were complaining of the very small incomes received from their farms. I was told that money loaned at five per cent. would pay them better than if invested in land at $100 an acre. Well, of course, in order to make land pay a good profit at that price, every available foot of it must be utilized. It is not an uncommon thing on farms of 160 acres, to find three and four miles of fence. Here is the point: I found that on many of the farms, briars, bushes and weeds had been left to grow and spread for years until, by actual measurement, I found a space a rod wide devoted to a fence-row, where not more than two feet ought to be occupied. Now supposing that on a farm having four miles of fence, half a rod more ground is given to the fence-row than is necessary. Here are four acres out of the 160 that are actually useless—yes, worse than useless, as they are sure to produce weed-seeds to stock the adjoining fields. Here, then, are $400 lying idle, which, at five per cent. interest would produce an income of $20 a year; or 2 2-9 per cent. of the income from the cost of the entire farm. Now there isn't a farmer in Western New York who would think for a moment of allowing $400 or any other amount to lie idle without a cent of interest; and yet this is just what many of them are doing by allowing so much of their land to go to waste. Is it any wonder they complain because "farming don't pay?" J. T.

EARLY PLANTING OF COTTON.—This year has further demonstrated the fact that we put off planting cotton till too late a date. It has been customary in this section to plant at any time from the first to the 20th of April, while some advocate planting the first week in May. I planted some this year myself on May 21; but as very little cotton came up till June 10, it did not make much difference when it was planted. There were in this section a few patches of cotton that were planted in March—something I have never seen before. They got a good stand, and although the whole spring was cool and backward and corn was bitten down by frost, the cotton was not injured, and it is the finest in this section to-day. Seven years ago we had a cold spell in May; people worked in the field with their overcoats on; corn was bitten down by frost; cotton shed all its leaves, leaving just the naked stalk sticking up out of the ground entirely denuded of its foliage, still the stand was not seriously injured. People had to plow and hoe the naked stalks until the weather turned warm, when the crop grew right off as if nothing had been the matter. This year and two years ago I failed to get a stand owing to a droughty April and I have resolved to profit by experience (which I have paid very dearly for) and hereafter, if I can prepare my ground in time, I shall plant in March or in the first week in April. I also advocate the early planting of both sorghum and Peruvian potatoes. I have tried them for years (both early and late) and pronounce early planting the great desideratum. G. H. F.

Denmark, Mississippi.

EXPERIENCE WITH SQUASHES.—I have always had very good luck with squashes, generally keeping some until the Fourth of July and some years until October. Last year was an exception. On account of the freeze in October they did not keep until April, although I had over 60 very nice specimens of the Orange variety, which are extra early, (thanks to the RURAL for them) until this freeze so early in the fall. Before the present year I never planted until June 20 to 22; but this year I planted June 1, and to get around the maggot, I sifted a half inch of coal ashes on each hill when planting, and so far they have been perfectly healthy. The maggot has been the only drawback to early planting and if coal ashes will stop its work, we shall get larger squashes, for they will have a longer time to mature. I always plant five seeds in a hill, and when the vines are coming up they must be kept covered with plaster. I look to them after every shower—not once a week as some do, but every day. I keep the ground mellow. I plow twice before planting, and after they have been kept clean, just before the vines begin to run, I plow the whole surface between the hills and give level culture and that discourages the weeds. I have 100 hills planted 4x6 feet apart. After the bugs have left, I thin out to two plants, and now, July 15, the vines nearly cover the ground. Cucumbers for pickles I plant in drills, six to 10 plants to the foot, after they are thinned. I keep them covered with plaster when they are starting or while young. P. C.

Milford, N. H.

ALSIKE CLOVER.—This year again proves the hardiness and the capacity of this plant for remaining in the ground during the winter and early spring, two features of much value to the farmer. Although Alsike hay is not as heavy when cured as Timothy or Red Clover, yet it is readily eaten by all kinds of stock. A good stand of this clover seems to insure a crop of it for years. As an illustration, an Alsike field was cut for seed four years ago, plowed and planted to corn the following year, then to barley, with rye in the fall and then seeded with Timothy and Red Clover, equal parts, without any Alsike. This year the Alsike is thick and heavy enough to warrant my saving it for seed. A yield of from five to eight bushels per acre pays very well as the hay makes good sheep feed after it has been thrashed.

One winter I kept a flock of ewes almost entirely on this thrashed hay with a small daily allowance of grain. It must be remembered that there is generally considerable well-cured Red Clover and Timothy in the hay. Besides the hay and seed produced, if the farmer will only keep a few colonies of bees, he will be repaid many times for all the seed sown, in the delicious honey. C. C.

JOYS OF THE FARMER.—New Jersey farmers have another enemy to contend with this season by way of variety. A green aphis has attacked their muskmelons in countless numbers. The pests infest the young and tender ends of the growing vines, causing the leaves to curl, and impairing the growth just as the Black Aphis injures the young growth of the cherry trees. As they are on the under side of the leaves they are thoroughly protected by the curl so that they cannot be reached by the ordinary application of insecticides. The only way it seems possible to reach them would be to dip the ends of the vines in some killing liquid, which, to be effective, would probably kill the vines too; besides, owing to the labor, it would be impractical and ineffectual as the pests are suckers. An army of parasites or a dose of dry weather would probably be the best remedy; but the damage being done already, Nature will probably take her own course, and we will go melon-hungry. Potatoes—well, they are going and gone in many instances—another legacy from the wet season. Verily the farmer's vocation is a happy one. Is it any wonder he is envied?

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

THIS summer the low-cut bodices with turn-down lace collars are very much worn. In some cases they are really too low to be lady-like on the street; the prettiest style is where the basque has no collar but the turn-down of lace, just the least bit open in a point in front.

* * *

MOIRE ribbons with a picot edge are now out of date; the coming ribbon is moiré with a broad satin edge. Do you know how moiré or watered ribbon is made? We saw the process recently; the ribbon is woven a plain gros-grain; then, in the finishing, it passes over pieces of wood set up like a banjo bridge and cut into an irregular surface. It is pressed upon these so tightly as it passes along that the ribbon is deeply marked. It then passes between rollers heated by gas, which, while flattening it, make the marking permanent. In making the picot edge a slender thread of flexible whalebone runs down either side of the ribbon, alternately catching in a certain number of threads of the filling, and then dropping them for a space. The piece of bone is about a yard long, slipping out of the ribbon as it lengthens.

* * *

NOW is the time to think about Christmas presents. They should be decided on months beforehand: whenever the purse allows it, some expenditure may be made. When fancy-work is selected, it should be begun early, so that there will be no hurry at the last. It is not at all a bad idea to make a list of the articles required or thought of, and somehow, things seem to cost so much less when they are bought by degrees than when everything is spent at once. Those round Japanese baskets make pretty and inexpensive gifts; the small ones are handy to stand on a bureau, and the larger ones as scrap-baskets or receptacles for odds and ends. They should be gilded in any color, and trimmed with ribbon bows.

* * *

A VERY pretty and very cheap wall decoration consists of a Japanese paper banner slanting diagonally; across the top five tiny paper lanterns are hung, while several little fans are laid across the bottom.

AFTER-THOUGHTS.

OLIVE E. DANA.

WE are often willing to do anything for each other save to exercise continually that willing forbearance, that generous thoughtfulness, that quiet, self-forgetful, burden-bearing love, which, *in exercise*, is the best gift we can render. We are often ready to make great sacrifices when we cannot bear patiently or in silence some petty misunderstanding of our mood or motive, and will not yield our will or way without complaint.

Ah! the little thorns! How they prick and sting and pain us! They wear away the good purposes, and waste the strength, and chill the love, and dim the trust; and they put frowning faces and sharp words in the place of our coveted serenity. They torture the nerves and rasp the temper, and put the soul in tumult. The little thorns—how do they grow so fast and thick? And do we not all of us help plant and tend them?

It seems to me that one of the worst things about our little fretfulnesses and despondencies is the way they are perpetuated and reproduced in others. We pass them on by the very expression of them, and without meaning to. And have we not noticed, sometimes how the complaint or repining did not spend itself in the utterance? Even the one that listened—willingly or unwillingly—and tried to give only the soft answer, yet very likely, afterward, could neither get rid of it nor away from it. And very likely she was more easily upset by the next small grievance that came to *her*. Haven't we seen a petulance passed on so from member to member of a household, changing in each from fretfulness to depression, from repining to hasty speech, from unwonted gloom to unusual nervous irritability, according to the disposition or temperament of each, as it went the rounds? And how much better it would have been if it had not been passed on at all! "Woe unto the world because of offences! for it must needs be that offences come; but woe to that man by whom the offence cometh." That is one warning we need to remember. And there is another we might oftener recall about the forgiveness without which, often repeated, there can be little real forbearance—"not until seven times, but until 70 times seven."

That is a pleasant and a suggestive passage in "Mary Clemmer's Memorial of Alice and Phoebe Cary,"—when she says:—

"Nothing could have been more absolutely harmonious than the daily abiding intercourse of these sisters. This was not because they always thought alike, nor because they never in any way crossed each other, nor was it based on their devoted affection and perfect faith in each other alone. People may believe in each other, and love each other dearly, and yet live in a constant state of friction. It was chiefly because each cherished a most conscientious consideration for the peculiarities of the other and because in the minutest particular they treated each other with absolute politeness. There is such an expression used as 'society manner.' These sisters had no manner for society more charming in the slightest particular than they had for each other. No pun ever came into Phoebe's head too bright to be flashed over Alice, and Alice had no gentleness for strangers which she withheld from Phoebe. The perfect gentlewomen which they were in the parlor, they were always, under every circumstance . . . . Each obeyed one inflexible law. Whatever she felt or endured, because of it she was not to inflict any suffering upon her sister; no, not even if that sister had inadvertently been the cause of it. If she was out of sorts, she went into her own room, shut her door and had it out by herself. Whatever shape her Apollyon might take, she fought with him, and slew him alone. When she appeared outside it might strike one that a new line of pain had for the moment lit upon her face; that was the only sign of the foe routed. The bright

sally, the quiet smile, the perfection of gentle breeding were all there, undimmed and indestructible."

Perhaps it is with the graces of gentleness and patience, forbearance and serenity as it is with many other things—we simply are not willing to pay the price we must pay to win them. Or perhaps we do not see quite clearly what that price is. Surely they are to be sought and cultivated, if many of us ever possess them. As is said of the Quakers, in that delightful book, "A Quaker Girl of Nantucket," "They are serene from principle and then from habit;" so it must be with any tranquil patience we attain to. There is much implied in that line from the last chapter of the Book of Proverbs, where is painted as nowhere else, the ideal woman: "In her tongue is the *law* of kindness."

LETTERS TO A COUSIN.

MY DEAR COUSIN: You will pardon, I know, my little delay in writing to you, for I have been entertaining an old friend and reading a new book, and between the two, I have not had a moment to spare for you, dear. Possibly, I might have stolen away from my friend (this is whispered very softly), but I really could not tear myself away from the book. Even now, thoughts about the book are uppermost in my mind and I think I must beg your kind indulgence while I talk about it for 10 minutes. It is "Looking Backward" by Edward Bellamy, that has interested me so deeply. I may not be the first one to speak of this book to you—I am very sure I shall not be the last. Like that much-talked-of book "Robert Elsmere," it treats of the universal brotherhood of mankind. The author very ingeniously dates his narrative in the year 2,000, and gives a retrospective glance over the faults and vices of the nineteenth century. In the twentieth century it appears that the United States Government has taken unto itself the full control and management of all the industries of the country, and in return it guarantees to every man and woman (*and woman*, mark ye that!) an education, employment and a competency for life; to each one the same amount—even as a father divideth his property equally amongst his children. The school education begins at the age of six and ends at 21. On this subject the author says: "No single thing is so important to every man as to have for neighbors intelligent companionable persons. There is nothing, therefore, which the nation can do for him that will enhance so much his own happiness as to educate his neighbors. When it fails to do so the value of his own education is reduced by half, and many of the tastes he has cultivated are made positive sources of pain." "To put the matter in a nutshell, there are three main grounds on which our educational system rests: First, the right of every man to the completest education the Nation can give him on his own account, as necessary to his enjoyment of himself; second, the right of his fellow-citizens to have him educated as necessary to their enjoyment of his society; third, the right of the unborn to be guaranteed an intelligent and refined parentage." These thoughts are ideal thoughts, cousin, but who can say that they shall never be realized.

Of employment he says: "All men who do their best do the same. A man's endowments, however God-like, merely fix the measure of his duty. The man of great endowments who does not do all he might, though he may do more than a man of small endowments who does his best, is deemed a less deserving worker than the latter, and dies a debtor to his fellows. The Creator sets men's tastes for them by the faculties He gives them; we simply exact their fulfillment." Dearest, did you ever hear anything more clear-cut and logical than that? Arguments, such as these are very beautiful. Pray, wait one moment before you denounce the ideas as altogether impracticable.

After leaving school, each person works for the government three years at whatever work he is appointed to. At the end of that term, he is allowed to choose his own vocation; if at the end of five years, he feels that he has mistaken his calling, he is allowed a second choice; this last he must abide by until the age of 45, when the government retires him from the service. Rather young to be laid on the shelf, you will say. But that is not the idea. Being released from government duties, each person may work for his own pleasure—not to lay up gold, for there is no money in circulation—but to advance in knowledge and understanding, "ever onward and upward," or to dabble in art and make poetry to his heart's content if so disposed; for, having honorably discharged his duties to Uncle Sam, his income is steady and secure year in and year out. There are no drones in this grand industrial government, all are actual producers and therefore the real wealth of the country is vastly increased.

Of course, you will have to read the book for yourself to understand "how all these things can be." The plans are all very finely made, and could they be fulfilled, peace and prosperity to all would seem assured.

According to the book, all civilized countries have adopted this new form of government, so that one may travel all over the world on his credit cards. Here is a bit of a criticism on authors by a 20th century woman: "Ah Dickens! you" (speaking to a 19th century man, who has been brought to consciousness after 43 years' sleep) "admired him then! That is where we moderns agree with you. Judged by our standards, he overtops all the writers of his age, not because his literary genius was highest, but because his great heart beat for the poor; because he made the cause of the victims of society his own, and devoted his pen to exposing its cruelties and shames. No man of his times did so much as he to turn men's minds to the wrong and wretchedness of the old order of things, and to open their eyes to the necessity of the great change that was coming, although he himself did not clearly forsee it." I know you will think I am the most sanguine person in the world, to even have faith enough in a scheme of this kind to write to you so earnestly about it; but if the subject does not arouse your sympathy I may at least hope that it will amuse you.

I was very much amused myself with this passage: "There is actually nothing that the people take more interest in than the perfection of the catering and cooking done for them, and I admit that we are a little vain of the success that has been attained by this branch of the service." "*Actually nothing that the people take more interest in than the perfection of the catering and cooking done for them.*" Ah, me! Is this advancement onward and upward? No subject then, even when we shall have reached the millennium, will be of greater importance than cooking! Let us proceed with our canning and pickling and preserving, and see who can make the "beautifulest jell that never was," in order that our children's children may with one accord pronounce us great. This is the only little slip I can find in the book that goes to show that human nature will be exactly the same then as now. You have doubtless received letters ere this that were all on one subject, (love letters for instance) and I trust you have not found this one more tedious than some of them.

Very affectionately your cousin,

DOCIA DYKENS.

GOLDEN GRAINS.

BERTIE: "Pa, is that new Mr. Hanks an ice dealer?"

Pa: "Yes, Bertie, how did you know?"

Bertie: "I didn't know, only I thought he was, for when the minister prayed for hot weather yesterday he said 'Amen!' awfully loud."..... .....

RUSKINS says: "Though you may have known clever men who were indolent, you never knew a great man who was so; and when I hear a young man spoken of as giving promise of great genius, the first question I ask about him is always: Does he work?".....

THE pious man and atheist always talk of religion. The one speaks of what he loves, the other of what he fears, says Montesquieu.

"SEEING we have such hope we use great plainness of speech." Ministers of Christ have plain truths to declare to plain people, and should declare them with such plainness that those who hear them shall be left without excuse in case they disobey. There should be such simplicity of language that a child can understand it, and such earnestness of soul that all who hear the word may feel its power.....

SAYS Mr. Spurgeon: "The reformation banished an unknown tongue from the reading-desk; we need another to banish it from the pulpit. The language of half our pulpits ought to be bound hand and foot, and with a millstone about its neck cast into the sea; it is poisoning the 'wells of English undefiled,' and, worse still, it is alienating the working-classes from public worship."....

BUILD a full, firm fence of faith
All about to-day;
Fill it in with useful works,
And within it stay.
Look not through the sheltering bars,
Anxious for to-morrow;
God will help whatever comes,
Be it joy or sorrow.

THE INDEPENDENT says that life, in the union of an individual, personal and immortal spirit with an animal and mortal body, is an insolvable problem. The severance of this union that takes place at death, is a problem of equal mystery. We cannot penetrate to the interior depths of either, and must hence content ourselves with our own ignorance....

THE fact that the good or evil which one does while living may long survive him in the results thereof, and thus make him a blessing or a curse to the world after he has personally left it, ought to operate upon every man as a powerful motive. It is a great and startling fact attached to the economy of our present existence, and immensely augments our responsibility.....

EVERY man, says Dr. Hanaford, has an "inalienable right" to a supply of 25 cubic feet of pure air each minute, that his blood may be reasonably purified, while the man, or monster who voluntarily so contaminates it by tobacco smoke that it is unfit for his legitimate use, is a usurper, a practical tyrant, and should be treated as such. No man has any better right to rob me of the pure air which the Creator has granted me than he has to steal my pocket-book, since the air is one of the necessaries of health and life .....

Domestic Economy

CONDUCTED BY MRS. AGNES E. M. CARMAN.

EXTRACTS FROM SUNDAY-EVENING TALKS AT THE RURAL GROUNDS.

IN the fourth chapter of Proverbs, the 18th verse, I find these lines: "The path of the just is as a shining light that shineth more and more unto the perfect day."

What I have to say is perhaps my own creed in part. The path of the just, I understand to be the experience or life of a good man. This was written before Christ came, and when the term Christian was unknown: faithful followers of God were then spoken of as just, righteous or upright in all their ways. If I use the term Christian instead of just man, it will be because the term is more familiar to us, and suggests the same idea more fully to our minds. The Christian life, then, is compared to an increasing glory of light. On a cloudless morning, if awake while it is yet dark, and watching for the morning, we would see how the light shines more and more to the perfect day. It is so dark just before dawn on a moonless night that to one uncertain of the time daybreak seems hours away, but a faint light or rather a little lessening of the darkness soon becomes perceptible; then it deepens to a gleam in the East, spreads toward the zenith, and slowly begins to bring out the objects around the watcher; but this early light often brings with it a sense of chill and desolation. The glory of the stars pales, and there is no joy in the heavens or on the earth; but the light soon deepens; the sky begins to flush with lovely color, and as the watcher begins to feel the glow of the new day, the sun's rays strike the earth and bring out a joyous sense of life in every living thing. In an hour it is perfect day, and the sun is doing his mighty work in silent faithfulness.

There are 365 mornings in a year; there may be 90 years in a life-time, and no two of all the 32,850 mornings dawn in just the same guise; but there is never a morning when the deep darkness suddenly becomes brilliant noon with no transition time.

So with the Christian life in the history of the church and in the lives of individuals. Perhaps our Christian life here is only the hour of the dawn, and the whole perfect day lies beyond in the country where we are told, "there is no night there."

If the Christian life were like the blazing of a torch when once lighted, the light could never increase and could not touch and quicken other lives more than a torch can hasten the circulation of the sap in tree and plant. It could not store up, by its shining, food and fuel and clothing in the earth and on the earth for the needs of the creatures it shone upon. If our lives are but torches, what increase of power have we to look forward to? The Bible is called a lamp, but the soul it illumines is compared to the shining light that shines more and more unto the perfect day.

The heaven promised the Christian has glories, Paul tells us, which "eye hath not seen nor ear heard, neither have entered into the heart of man the things God hath prepared for them that love him;" and a little further on, in the same letter, he says: "But the natural man receiveth not the things of God;" showing that we are to be changed and fitted to enjoy the promised heaven.

To become purified and strengthened in every faculty must be in itself a great and never-failing joy; and to be placed where the ear, attuned to harmony, will hear rarer music than we can imagine; where the sense of beauty, intensified and deepened, will see fairer sights, and the mind can follow unbroken chains of living thought—all this will be a part of the perfect day, and all this will be reached by transitions from our feeblest beginnings here, through every intermediate step.

Christ described the Kingdom of God "as if a man should cast seed into the ground and it should spring up and grow he knoweth not how—first the blade, then the ear, then the full corn in the ear." Paul spoke of "babes in Christ whom he fed with milk and not with meat, because they were not able to bear it."

If, then, we *grow* in grace instead of becoming full-grown and perfect at once, what is our guide? For growth means constant change, and change means new experiences and many uncertainties. Is our conscience, our sense of right and wrong, a safe guide? It is certainly a guide we must follow, for we sin wilfully when we refuse to do what we believe is our duty, but we may sin and yet follow faithfully our conscience. Look at the life of Paul. He first appears in Bible history standing by and consenting while Stephen, a Christian (the first Christian martyr) is stoned to death. Then we hear of him through his own confession as zealously persecuting this new sect. He says: "Beyond measure I persecuted the Church of God and wasted it." And in his defense before King Agrippa when imprisoned himself for Christ's cause: "I thought verily with myself that I ought to do many things contrary to the name of Jesus of Nazereth." But when it was revealed to him that Jesus was the promised Messiah, the son of God, he did not cling to his old belief because conscience had guided him then, but he gave his conscience a new command, whereupon he says: "I was not disobedient unto the heavenly vision." Conscience then *holds* us to our purposes; reason must be our guide.

Were the intricate, delicate web of the brain and its reasoning made only for those who disregard the voice of conscience? No, and God who wove the minute and marvelously sensitive filaments of the brain, will illumine its powers. James in his letter to the early Christian Jews wrote: "If any of you lack wisdom, let him ask of God that giveth to all men liberally and upbraideth not, and it shall be given him."

This gift of wisdom comes slowly, not in one great flash of dazzling light; but surely, and as we need it, if we "ask in faith, nothing wavering." Conscience, then, we must obey, but we will find our sense of right changing, growing better and truer if we remember that the conscience must be given new commands with every new ray of light that comes into our souls as we come nearer and nearer to the perfect day. We must look to a thousand sources for helps for our reason—our own past experience, the experience of friends, the experience that has been written out for us in good books now and in the past, especially the experiences given in the Bible carefully preserved for us and inspired by God's truth. But wherever we look for helps we must ask God to illumine the reason he has given us that we may follow a conscience leading us in the right way, toward the yielding in our lives, of the fruits of God's Spirit, which are these: "Love, joy, peace, long-suffering, gentleness, goodness, faith, meekness and temperance."

Do your housework quietly—it is less tiresome—and remember that the quiet worker accomplishes the most.

A FEW WORDS ABOUT VISITING.

DORA HARVEY VROOMAN.

WHEN I was a very young girl, just "coming out," an old Quaker lady, a friend of the family, said to me:

"Let me give thee a little advice. When I was a girl my mother used to say to me, 'Annie, thee must never be the first to go to a

Miscellaneous Advertising.

When Baby was sick, we gave her Castoria
When she was a Child, she cried for Castoria
When she became Miss, she clung to Castoria
When she had Children she gave them Castoria

party or company, and neither must thee ever be the last to leave.' "

"But," said I, "If you are supposed to come at half past eight, should you not be there on time?"

"It will do no harm to be on time, but do not be ahead of time, as so many people are on such occasions. Let the older folk come early if they like, but do not thee do it. And again, continued she, "if thee says thee are going, go. At a gathering of any kind it will not matter so much as it will if thee are spending an afternoon. If thee are invited to tea, accept the invitation or refuse it as thee sees fit; but if thee *does* accept it, *go* and in plenty ot time before tea."

This latter piece of advice I have found in my experience to be excellent, and it is because of this very thing that I write on this theme at all. Let us instance a case: We may have a caller; the afternoon passes quickly, and before we realize it. we find it waning. We invite our guest to stay to tea.

"Oh! no, indeed, I cannot," she exclaims, "Mamma will be expecting me home"—but she does not go. She talks a little longer, then again exclaims "Oh! dear, I really *must* be going!"—but she continues talking and still does not go. Meanwhile "Bridget" (if one is fortunate enough to "afford" a maid) is getting tea. Perhaps we had instructed her in the morning as to what we would have. But if our guest had accepted our invitation, we would have altered our bill-of-fare somewhat. Or if we do not keep a maid we are detained from getting tea, and "Jack" will soon be coming!

At last she jumps up saying laughingly: "I really ought to be half-way home by this time" —puts on her hat, fusses with her gloves, then says, "By the way, I have something important to tell you, and to think I almost forgot it!" Then she discloses some wonderful (?) story that is being gossiped about, gets as far as the door, kisses us good-bye—but, instead of actually going, she stands on the step, still giggling about nothing, never realizing that we are worried or anxious. Then the gate latch clicks. "Jack" has come! She greets him and he cries: "What! going? You will surely stay to tea?"—She demurs a little, but finally returns to the parlor. You rush off to the kitchen. If you have a "Bridget" perhaps you'll find she has put on a crumpled table-cloth, which you had meant for the wash, so you must either make the best of it, or take everything off the table and re-set it. But if you are your own "Bridget!" Words almost fail me, for—I know whereof I speak. The fire is either out or very low. You add a few chips or blocks of wood to hurry the kettle up. You poke it a wee bit, and get down on your knees in front of the grate, and blow to make it draw. But it won't! You blow again. Suddenly without a moment's warning, a great puff of smoke followed by some long tongues of flame bursts out into your face. You narrowly escape being burned, the tips of your bangs are singed, and you are covered with white ashes from the top of your head down. You are half suffocated in the bargain. Then you turn your attention to arranging the table; while the tears, caused half by smoke and half by nervousness. are trickling down your cheeks. At last tea is ready! You summon "Jack," and your caller. Amid all your flurry and worry, you have heard their voices and every now and then a merry peal of laughter. They come at your bidding. Your visitor looks cool and collected, while a bright smile plays around the corner of her mouth. "Jack" looks at the dainty supper; then at your flushed face and exclaims:

"Why what's the matter little girl—are you sick?"

You don't thank him a bit for his sympathy, for this only calls your visitor's attention to your looks But men *never* know anything! You try to silence him by a fierce glance, and attempt to make some agreeable reply. But he—the big, good-hearted fellow—can't understand, and insists on knowing if you really are ill—wants to get something or do something for you. If you are of an especially nervous nature 10 to one you'll cry. Then your nose will look redder than ever, and your caller will look cooler and sweeter than ever. (That is always the way!) You'll murmur something about a headache, which won't be a falsehood either, for in all probability you will feel as if a dozen blacksmiths were at work inside of your cranium, trying to finish up a contract immediately. You don't eat much—"Jack" knows something is wrong, but can't tell what, so he doesn't eat much either. After tea you chat a little, then your visitor really does go. Perhaps you and "Jack" must take her home or to the cars. It will be safe to say that you don't much regret her going, and it will also be safe to add that you won't yearn for her coming again in a hurry.

Now if she had accepted your invitation to tea, you would have excused yourself for a few moments, gone and instructed "Bridget," or in the absence of the latter, you would have attended to the fire, put the kettle on so that it might boil by the time you were ready for it. Then, just before it was time for "Jack" to come, your guest might have come into the dining-room while you arranged the table. But, when she was going every instant, how could you do anything? When "Jack" did come, in the latter case, tea would be ready. You would all sit down together and have a merry chat. You would be in your normal condition, and would doubtless say to "Jack" when your visitor had gone:

"Don't you think Miss Blank a pleasant girl? We've had such a delightful time, that I hope she'll soon come again."

Of course, all I've been saying applies only to people in moderate circumstances, yet this very practice is often disagreeable even in wealthier circles. It is said of M'me de Stael that even she, though eloquent and refined to the highest degree, failed just here. She never knew when to stop talking, or when to go. It is related of her that while traveling through the continent she one day at breakfast announced to a lady where she was visiting, her intention of leaving that day. Her carriage was ordered, but she had started a new theme and talked incessantly till luncheon. Then, of course, she was invited to remain and lunch with them. She did so. After luncheon she still kept on talking till it was almost dinner time. Her host and hostess could do nothing less than press her to stay and dine also. This she did and the conversation begun at the dinner table lasted till it was too late for her to go that night. She was invited to remain over-night. She consented, and her carriage, which had stood at the gate all day long, was dismissed.

You may be bright, witty, and entertaining, but perhaps you entertain yourself more than others. *Listen* sometimes as well as talk.

Another word or two about visiting before I stop: If you go to spend any length of time —a few days or a week—among friends or relatves in moderate circumstances, where the mother or daughter must assist with household duties, do not sit with idly folded hands, but assist where you can. You can attend to your own room, wipe the dishes, dust up the parlor or dining-room, etc. In this way the work will be done sooner and you will all have more time for social intercourse and enjoyment A visitor always makes more or less work, and unless your hostess is able to afford to keep a servant, or servants, to do this work, she, herself must do it.

To be sure the *honor* of your visit, as I once heard a young girl say, may recompense her; but it seems to me that I would simply make a formal call (if I went at all) when I felt myself so much superior. But any girl with common sense, or, as the old-fashioned people say, "mother wit," will soon learn what she may or may not do. Now, assisting in one thing, and prying about and being officious is another thing all together.

It is well, perhaps, for children to visit, as it throws them in contact with other people, and "smoothes down the corners," but I would advise mothers to let it be short, unless there is an older person along to take care of them—But I am wandering from my theme!

This uncertain, wavering way that so many of our girls and women have about wasting time, is what goes a great way towards making society such a hollow pretense of friendship. I do not see (though no doubt I'm a heathen), why I should call or go anywhere where I do not care to go. There's one thing about me, however, that may always be depended upon at any rate: *I never ask anyone to come and see me unless I want him or her to do so.* People so often say: "Come and see me," while all the time they hope you won't do it. I was visiting a friend a short time ago when another lady called. She stayed only a litle while. When she was going my hostess said: "I'm sorry you can't stay any longer, but come soon again."

When the lady had gone I said: "Why I thought you didn't like Mrs. X—?"

"Well, I don't!" she replied. "In fact, I detest her, but I had to invite her to come again for decency's sake."

I didn't see it exactly. At any rate I determined to cut my visit short. I was having a very delightful time, but after that speech I could not help feeling that perhaps I was being pressed to stay for "decency's sake." I haven't gone there since, though I've received several invitations, and shall not go very often, for the knowledge that this lady, whom I had always cared for as a friend, was so deceitful in one instance prompted me to fear that she might be so in my case. It does really seem at times as if—

"This world is all a fleeting show,
For man's illusion given.
The smiles of joy, the tears of woe,
Deceitful shine, deceitful flow—
There's nothing true but Heaven."

Put in order the room you have been sitting in, before retiring for the night.

HINTS FROM CORRESPONDENTS.

WE have kept our hams perfectly through the warm weather by packing early in the spring in clean, sweet hay and keeping in a cool, dry place. A. G.

ALTHOUGH I am the dish-washer of the household, I have kept my hands presentable by rubbing them with lemon juice and oatmeal. MISS K. G. H.

OUR currant shrub is a perfect success this year. The juice was prepared the same as for jelly, except that it was boiled only 10 minutes. Bottle and cork when hot. Use small bottles. When wanted, use one-third of the juice to two parts of ice-water. We have found this a refreshing drink. MRS E. C.

WE think that steamed quinces served with powdered sugar and cream are excellent either as dessert at dinner or as a tea dish. MRS. I. B.

Velvet ribbon will be much used for trimming dressess this winter.

FRIED TOMATOES.

PEEL and cut in half-inch slices, salt and pepper, dip in wheat flour then in beaten egg and fry in hot drippings.

BAKED TOMATOES

SELECT firm good sized fruit. Cut a round piece from the top of each and with a spoon remove two-thirds of the inside. Fill the cavities with dry bread crumbs (very fine) seasoned with butter, pepper and salt and minced parsley and onion, if liked. Arrange in a tin, add a lump of butter and a little hot water and cook in a moderate oven for three-quarters of an hour, basting frequently. Cook the pulp taken from the tomatoes 10 or 15 minutes, remove from the fire and when cool press through a sieve. Season with butter, pepper and salt and thicken with a little corn-starch. Just before taking the tomatoes from the oven, pour a little of the gravy over the dressing in each. When taken from the oven arrange on a flat dish and pour the sauce over. Serve at once. MRS. ECONOMY.

PUMPKIN PIE.

STEAM the pumpkin until tender and when cool press through a colander. To a pint of the pumpkin add a spoonful of butter, a teacupful of sugar a, little salt and cinnamon to taste, a pint and a half of milk and a teaspoonful of corn-starch worked smooth in a little milk. Bake with an under crust. As the thickening property of pumpkin varies, some judgment must be used in adding the milk MRS. K. I.

The Aged

Who need help in their many infirmities, especially those afflicted with rheumatism, find great relief in

AYER'S Sarsaparilla.

"One year ago I was taken ill with inflammatory rheumatism, being confined to my house six months. I came out of the sickness very much debilitated, with no appetite, and my system disordered in every way. I commenced using Ayer's Sarsaparilla and began to improve at once, gaining in strength and soon recovering my usual health. I cannot say too much in praise of this well-known medicine." — Mrs. L. A. Stark, Nashua, N. H.

News of the Week.

HOME NEWS.

SATURDAY, August 31, 1889.

DELEGATES to the Congress of the Americas will meet in Washington on October 2. They will be the guests of the Nation, and before proceeding to business they will make a tour of the North and West to inspect their character and resources. This will probably last from October 3 to November 15. When winter sets in they will travel through the South. All the governments on this continent will, it is expected, be represented, and great hopes are entertained of good results from this friendly conference of all American interests..... An effort is being made to obtain a fit jury for the trial of the six men accused of murdering Dr. Cronin at Chicago. There is great danger that a Clan-na-Gael supporter may contrive to get in, to hang the jury instead of the murderers. The trial is likely to attract as much attention as that of the Anarchists two years ago. Two desperate attempts have already been made to assassinate witnesses against the accused. Nothing will be left undone by the desperate friends of the murderers to insure a miscarriage of justice. .... During the year ending June 30, 1889, out of the Federal Army of 22,000 men, there were 2,842 desertions, which cost the Government $600,000. This enormous rate of desertion in the best paid army in the world, is attributed to the neglect, abuse and cheating practiced on the enlisted men by the officers. Their faults are, no doubt, exaggerated, but the desertions still remain..... The poor whites are following the example of the negroes in abandoning the Carolinas. The Memphis and Charlestown Railroad has made arrangements to carry 400 white families from both States to Arkansas, and 8,000 negroes from both States to the Yazoo Delta in Mississippi; 3,000 more negroes have already gone on the same line; while other lines have also done a heavy business in transporting Carolina negroes to the West in spite of the efforts of planters to keep them at home..... ... A trust of paramont interest to farmers has just been completed—one to put and keep up the price of diamonds: a Diamond Trust.. The woolen men still continue to fail: the last to do so is J. M. Mackintosh of Milton, Mass., liabilities $100,000..... In spite of the discontent of the veterans at the refusal of the railroads to grant a one-cent-per-mile rate, the annual meeting of the Grand Army, at Milwaukee, Wis., is quite respectable in numbers. Tuesday over 35,000 men were in line at the grand parade, and 200,000 enthusiastic spectators made the welkin ring. Gen. Sherman, Mrs. John A. Logan and Pension Commissioner Tanner, appeared to be the hottest favorites. A large number of posts had formally resolved not to be represented on account of the obduracy of the railroads. The Commissioner says he is in doubt whether to ask for $110,000,000 or $115,000,000 for pensions for next year, a rise of about $30,000,000.. On Thursday his administration was most enthusiastically indorsed by the veterans, and his policy applauded to the echo..... .. ... Gen. Russell A. Alger, of Michigan, has been elected Commander-in-Chief for the ensuing year..... .... Jack Dempsey, the "Nonpareil," middleweight champion slugger of America, was "knocked out" in the thirty-second round by George La Blanche, the "Marine," in a glove fight in the rooms of the California Athletic Club, at San Francisco, last Tuesday night. Jack weighed 151 pounds; and George, 161; the odds were 100 to 35 in favor of the former before the battle. He defeated the "Marine" some time ago, and will have another fight with him soon. This is his first defeat in nearly 50 contests.....The Inman steamer City of Paris, has smashed all previous trans-Atlantic records—her own among them—by making the passage from Queenstown to Sandy Hook in five days, 19 hours and 34 minutes—four hours less than her former unprecedented record.....In analyzing congregational generosity Rev. James Brownlee finds that among the Baptists 36 cents is the annual contribution per head; the Methodists, 74 cents; Episcopalians, $1.37; Presbyterians, $3.17, and the Dutch, $5.21..... The most disastrous cloud-burst that ever occurred in North Carolina, happened near Rockingham, Richmond County, last Sunday night. It instantly swelled the Pedee River, and the mad torrent, far beyond its banks, swept crops, cattle, fences, houses, mills, etc., before it, doing a world of damage and causing several deaths. Eight cloud-bursts have occurred in the State Since May 1.....The charge against Justice Field, in connection with the Terry matter, has been finally dismissed by the California State authorities at the suggestion of the Governor. All the prosecuting lawyers have also withdrawn from the deputy-marshal Nagle case; but the question whether his action in shooting Terry is to come under Federal or State jurisdiction will be soon argued before the United States District Court at San Francisco..... A window and table glass trust is the latest, under the name of the United Glass Company. For 10 years the glassware business here is said to have been in poor shape. The object of the trust is, of course, "to save expense, cheapen the price and make a profit." There's some doubt whether the Western manufacturers will join.....The formation of the Crockery Trust is deferred "till next year."....."Down in Marion County, Ala., the other night a masked band of regulators took to the woods three proselyting Mormon Elders who had refused to obey a warning to leave, and having hung them up by their thumbs, flogged them unmercifully. Some married women they had perverted were warned to return home, under penalty of like flagelation. Lynch law is the common antidote for the poison of Mormonism in the South, where it finds more victims among the ignorant "white trash" than in any other part of the country.....

Jubilation.

MISERY adds to misery, sometimes, in our endeavor to escape it. Presently we are confronted by disheartening accumulation: we know not where to turn, and courage is almost gone.

But a beneficient providence opens the way, at sadly rare intervals, and then—Jubilation.

Here are a few notes of it:

LITTLE ROCK, Ark., March 30, 1888.
"I am happy to inform you that I am of the opinion that your Compound Oxygen saved my life." MRS. J. P. BAILEY.

BUNKER HILL, Ind., March 14, 1888.
"I feel that I cannot say too much in praise of the Compound Oxygen Treatment."
MRS FLORENCE BLUE.

OSWEGO, N. Y., Oct. 30, 1885.
"Compound Oxygen has greatly benefited me. Under God it has given me new life."
REV. JOHN C BREAKER.

MANCHESTER, Me., Feb. 22, 1888.
"Both myself and family believe that I owe present existence to your Treatment."
M. A. CUMMINGS.

We publish a brochure of 200 pages, regarding the effect of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia; all chronic and nervous disorders. It will be sent, free of charge, to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa., or 120 Sutter Street, San Francisco, Cal.—*Adv.*

AGRICULTURAL NEWS.

SATURDAY, August 31, 1889.

AFTER Axtell, the three-year-old trotter, had made a mile in 2:14 at Washington Park, Chicago, on August 23, breaking the record of trotters of that age, Col. Conley is reported to have offered $100,000 for the colt to Mr. C. W. Williams, his breeder and owner; but the offer was declined. The rumor of such an offer, even if it was never made, or if made by collusion, simply as a friendly puff, is a big advertisement for the owner and the trotting tracks where the phenomenon may hereafter appear..... .....Last Sunday, Henry Shaw, the philanthropist and best friend of St. Louis, died at his home in St. Louis at the age of 89. An Englishman by birth, born in 1800, he came to this country in 1819, settled in St. Louis, then a petty place, in the hardware trade in a small way. In 20 years he amassed a fortune large enough to induce him to retire from business. After traveling the world over, he devoted his attention to the study and cultivation of plants and flowers, and set out the now world-famous botanical garden known as the Shaw's Garden. Some time ago he gave to St. Louis the splendid Tower Grove Park, and he has also bequeathed to it Shaw's Garden and most of the $2,500,000 he has left behind him..... To a letter of inquiry from Governor Wolfley, of Arizona, Acting Commissioner Stone of the General Land Office, has replied that while the act of June 2, 1862, makes a grant of public lands to such of the several States as may establish colleges for the benefit of agriculture and the mechanic arts, it is his opinion that it does not apply to Territories before their admission into the Union as States .. ....The great Granger's Inter-State Picnic Exhibition opened at Williams Grove, Pa., on Monday. The exhibition is superior in all respects to that of any previous year and the attendance so far has been very large—larger than ever before. Should the weather continue favorable, it will be the largest meeting of Grangers ever held in this country..... The Brooklyn Kennel Club and Poultry Association's show will be held from September 9 to 11. Over $1,000, besides medals and diplomas, will be given as premiums for dogs and poultry. Information will be furnished by T. Farrer Rockham, Superintendent, East Orange, New Jersey..... Mr. John W. Akin, of Scipio, New York, importer of Percherons and French Coach horses, had six valuable pure-bred Percheron stallions injured on a barbed wire fence, during a recent terrific thunder storm in the night: 21 stallions went through a six-wire fence in three places, breaking off 31 solid posts and tearing off 20 rods of wire. All except one of the injured horses are doing quite well. Mr. Akin arrived at "Elmwood" with his latest importation of French Coach stallions, August 28.... The North Dakota Millers' Association has decided to place an agent in London to dispose of flour direct to the bakers of Great Britain. It is thought this will have a strong tendency to strengthen the home wheat market, and, besides, will result in the building of a number of new mills ..... Ten thousand tons of wheat were burned in San Franciso on Monday, and Texas fever is reported to have broken out with the utmost virulence among the herds in the West. Such visitations are rank calamities so long as the sons and daughters of men live upon bread and meat.....Twenty-five million dollars' worth of hides were imported into this country last year duty free. A vigorous effort is to be made during the coming session of Congress for the restoration of the tariff duty repealed in 1872. Opponents of the measure stigmatize it as "a bait to catch the cattlemen's votes."..... ..... There is a suggestion that wool-growers, though their attorneys, commission-men and other friends, should step in and run the forthcoming woolen manufacturers' conference at Boston. Wouldn't this reverse the usual order of things—turn the tables on the manufacturers? .. ..

Crops & Markets.

SATURDAY, August 31, 1889.

ONCE a year representatives from all European countries hold a Grain Congress in Vienna, Austria, in August. Estimates are then made of the grain crops of the world for the current year, the figures being based on the most reliable attainable data. The results reached have a good deal of influence on the prices of cereals—for the next few months at any rate. Last Monday a brief abstract of these results was cabled to this country. The figures, to say the least, are startling. It appears that the European grain crop was 15 per cent. short. The grain crop in Russia, Austria, Hungary and Roumania will not exceed 160,000,000 bushels this year.

Advices from the West say that all the important surplus corn areas, such as Nebraska, Iowa, Missouri, Kansas, Illinois, Indiana and Ohio, have, for the first time during the present growing season, enjoyed a period of uniformly seasonable temperature for nearly 14 days. The results are perceptible; first, in the very large and free movement of old corn, a good movement of oats and a fair movement of wheat, secondly, the weather has been all that could be desired for thrashing the oat crop and finishing up of the harvest of the spring wheat, and, last but not least, exceedingly favorable for helping out the backward corn crop. The danger line, so far as an early frost is concerned, is thought to be over. Complaints are made of low prices for oats, and corn is dropping in price every day. At interior points of production from Nebraska to Illinois, oats to-day will hardly average 16 cents a bushel. Indications are that, as a rule, farmers will not hold their crops for higher prices this year as much as they have been doing of late.

The latest San Francisco estimates of the California vintage indicate that it will not exceed 12,000,000 gallons this year. This is a reduction of 8,000,000 gallons from early estimates of this year's vintage. This is due partly to damage by sunburn and mildew, but more especially to the fact that the drying of wine grapes will absorb probably 2,000,000 gallons, while 4,000,000 will go into the still. It is also estimated that the State will produce 1,000,000 gallons of brandy this year, brandy to a large extent superseding wine.

LATEST MARKETS.

PRODUCE AND PROVISIONS.

NEW YORK, SATURDAY, August 31, 1889.

NEW YORK MARKETS.

WOOL.—Spring Texas, 17@23c, and Fall do 20@25c; Fall California, 11@18c, and Spring do 18@21; Scoured Texas, 52@53c; Delaine, 36c; Indiana, 29c; Scoured Territory, 55c; Donskoi, 24½c; XX Ohio, 34c; Scoured Colorado, 53c; Australian, 38c.

EVERY FARMER HIS OWN MILLER DO YOUR OWN
Shelling and Grinding at home, saving tolls and teaming to and from the Grist Mill. This work can be done rainy, windy days when out-door work is suspended on the farm. The same Mill will cut corn stalks, saw wood, run churn, grindstone, pump water, etc. We make the HALLADAY Geared Wind Mill in 11 sizes, 1½ to 40 horse power, and GUARANTEE they have no equal for Power, Durability and Storm Defying qualities.

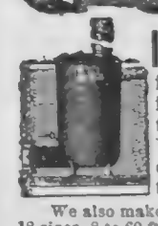
IXL 2-HOLE Corn Sheller
Adapted to run by hand, horse, steam or wind power. Not cheaply made but strong, durable and effective in its working yet light running. It is constructed similar to the large Power Shellers and is the best 2 Hole Sheller on the market.

HORSE POWERS and JACKS, both single and double Geared, made heavy and strong.

THE IXL STALK CUTTER
made in 5 Sizes, with Safety Fly-Wheel, Safety Lever, and all late improvements.

THE IXL IRON FEED MILL
3 sizes, both Belt and Geared Mills. Can be run by any power and especially adapted to Wind Power. Will grind any kind of grain and is the lightest running and most effective Feed Grinder made.

SAW TABLES
Both Swinging and Sliding Tables. We make a Saw Table especially adapted to sawing long poles. Special care is taken to make these machines strong and durable.



IXL TANK HEATER for warming water in Stock Tanks. Made of the best quality of iron cast in one piece, no sheet iron to rust or solder to melt and cause leak. Will burn any kind of fuel. It is very effective and takes less care to operate than any other Heater made.

We also make the HALLADAY PUMPING WIND MILLS. 18 sizes, 8 to 60 ft; diameter and 1 man to 40 horse power. The U. S. SOLID WHEEL WIND MILL, 7 sizes, Iron and Brass Pumps in great variety. Tanks, all kinds and sizes, and the Standard Hay Tools, consisting of Anti-Friction, Swivel, Reversible and Rod Hay Carriers, Harpoon and Grapple Horse Hay Forks, Pulleys, Floor Hooks, etc. All goods fully guaranteed. Send for Catalogue and Prices. Reliable Agents wanted in all unassigned Territory.
U. S. WIND ENGINE & PUMP CO.
BATAVIA, ILLINOIS, U. S. A.
BRANCH HOUSES:—Kansas City, Mo., Omaha, Neb., Fort Worth, Tex., Boston, Mass.

THE LADIES' HOME JOURNAL
Is the handsomest magazine printed and has a larger circulation than any other periodical in America—nearly HALF A MILLION (500,000) paid in advance yearly subscribers. The Autumn issues will be special editions—GRAND HOLIDAY NUMBERS—mailed to any address from now to Jan. 1890, for only 25 Cents, silver or stamps.
Some of the special strong features for the autumn are, a story by
Mrs. A. D. T. Whitney, treating of one of those ambitious suburban neighborhoods, built up on Queen Anne pretentions and imitations which also run through the social life. "Ascutney St." aping "Katahdin St.," which in turn tries to stretch up after "Shasta St."
Maud Howe is writing for us a story of social life that will prove a strong attraction. It is the story of a young American girl who goes to London and makes a great social success. It is first of all a love story, but unfortunately, the heroine first falls in love with a man who is not free to marry her, but later finds a better and truer lover, to whom she finally gives her hand.
Illustrated stories by
Josiah Allen's Wife, *Kate Upson Clark,*
Mary J. Holmes, *Kate Tannett Woods,*
Margaret E. Sangster, *Robert J. Burdette,*
Susan Coolidge, *Katherine B. Foote.*
Full page illustrated poems by *Will Carleton.*
Florence Howe Hall will contribute a series of papers on "Inelegancies and Affectations of Speech," "The Secret of Entertaining Company Agreeably."
Literary page—by MRS. A. R. RAMSEY and EDWARD W. BOK.
Fashions—by MRS. J. W BISHOP. Practical Housekeeping. Flowers and House Plants—by EBEN E. REXFORD.
Artistic Needlework—beautifully illustrated. Talks with Mothers—by eminent physicians.
For 25 cents we will mail you the October, November and December numbers, also a complete premium catalogue in which you can select from hundreds of useful articles. Premiums for clubs of trial subscribers at 25 cents each.
CURTIS PUBLISHING CO., Philadelphia, Pa.

Literary.

UNCLE BOB AND HIS CHILDREN.

SOMETIMES I feel like laughing at Uncle Bob, to see the way he manages or mismanages his children. Sometimes I think he is a goose, and then again, when I see how much he loves them and they him, and how most of them trust him, I think he can't be far wrong. I don't live very far from Uncle Bob, and I *have* to see and hear some things, whether I want to or not. I will not undertake to tell how many children he's got, but there must be somewhere from seven to 12. Most of them have pet names that fit about as well as if an elephant were nicknamed a snipe. There's something a little crooked and queer about the oldest boy. He's different from Uncle Bob and Aunt Bob and all the rest of the family. He has a voice like a fog-horn—I guess, although, living in Colorado, I never heard a fog-horn: but I've read up about it in the cyclopedia. Anyway, Uncle Bob calls this youngster "Sweet Note."

It is one of Uncle Bob's ideas to give each one of his children something. Perhaps he'll give one a colt, and another a calf, and another so many hills of beans. The other day I saw him give one of the little girls 55 cents for some cabbages he had sold from her row.

"How's this?" said one of the hectoring hired men. "How's this? Here you are taking money for cabbages you never planted, or irrigated, or plowed or hoed."

"Well," said the little thing, "I know I didn't; but I brought the young plants to Pa and he set them out and gave me any row I'd a mind to choose, and I chose the best of them all, and they are mine and I've got the money—and so!"

The little thing has the money up in her box stowed away, and when somebody's birthday comes, or Christmas, or a circus, or she wants a ribbon for her Sunday hat, Little Cabbages, (I've forgotten her nickname) will out with her money and spend it with great delight, and, most likely, for somebody else or for some article of clothing, and she'll do the business as circumspectly as many a woman. One day I spoke to Uncle Bob about it, and asked him if he wasn't afraid the youngsters would mis-spend the money?

"Bless your soul!" said he, "no. People have to be educated to handle money as well as to handle a hoe, or a horse or a sewing-machine."

Most of the children make Uncle Bob their banker. I heard one of the neighbor's boys saying to one of Uncle Bob's boys:

"Catch me putting my money into father's hands! He'd never let me have it when I wanted it." It isn't so with Uncle Bob.

But Uncle Bob had a picnic with Sweet Note, that I guess rather discouraged him for a while. The boy wanted a certain black filly that was just coming three years old. She was a proud stepper and swift. The boy was, like most other farmers' boys, capable of recognizing the best animal on the place. Said Uncle Bob, after long consideration: "Coal Dust is yours on these terms: I must be the judge of what work she shall do, and at what age you shall ride her, and how much. She shall never be sold except by my permission. If she is sold the purchase money shall be placed in the bank there to accumulate for you until you are 21."

All this was agreed to; but, O my! what a change the ownership of that mare made in the boy. He was so proud of his new possession that he got braggy. Then he grew almost insolent to his father when the latter cautioned him not to ride her very far.

"Look here, Pa," said he, "Do you think, for a minute, that I'd ride Coal Dust to death because she happened to be mine?"

"Not intentionally, but you might not use judgment and might very easly spoil her."

By and bye the boy got his heart set on a bicycle, and made offers to swap the mare for one. He carried the matter so high that Uncle Bob bought the mare at a small valuation which the boy put upon her—say, about half her true value. When the boy was tired of his toy you should have heard him beg But the father was firm, and I take notice he isn't giving the boy any more spirited fillies. Lots of folks can't stand prosperity. I remember one spring I was helping Uncle Bob to plant potatoes, when up marches a boy about 10 years old and says he: "Pa, how many potatoes may I plant and have for my own, if I'll get the seed?"

"All you'll find seed for," says the old man.

No more was said. After sundown off posts that small boy to the trash-pile where somebody had dumped some sprouted potatoes. He pulled one sack out of the edge of the river. Then he cut the potatoes as steadily as a judge. He gave me five cents to help him after chore time, in the dark. He dropped the potatoes and marked them and gave them a most all-sufficient hoeing. I believe he got five dollars, more or less, out of that happy thought. Pretty soon he says to his father, with his eye on a fine grade Holstein heifer—

"What's she worth, Pa?"

"O! about five dollars;" said Uncle Bob.

"May I have her for five dollars?"

"Yes."

"All right," said the boy. "Keep the four dollars you've got of mine, and I'll pay the rest some time."

Then he went to picking up bottles and old iron out of the trash and soon he had the other dollar. You should have seen that youngster skip when he had her paid for.

"Perhaps I'll have quite a herd by the time I'm of age," said the boy.

In four months' time Uncle Bob offered the boy $10 for his heifer, and the boy just laughed at him. Take it all in all, I do believe Uncle Bob and Aunt Bob have an amazing faculty for interesting their children on the farm. The other day I heard that two of the children were forming a partnership and going into the hen business. O. H.

MAGAZINE REVIEWS.

HARPER'S MAGAZINE for September has a long article by Theodore Child on American Artists at the Paris Exhibition. The fact is noted that in 1889 America boasts an élite of artists whose names are cited in company with the most illustrious, and who can hold their own brilliantly among the great masters. The number of oil-paintings exhibited in the United States section is 335; black and white drawings, water-colors, etc., 127; wood-engravings 103; representing 252 artists. The most eminent of all the American artists resident in Europe, James Mc Neil Whistler, exhibits his pictures in the English department. Reproductions are given of many of the most famous paintings, and many others are very vividly described. James Lane Allen gives "Kentucky Fairs" a very realistic pen-picture of a local institution peculiar to that State. The first fair was held in 1816, and was instituted by a distinguished soldier and honored gentleman with a taste for agriculture and fine cattle, who announced that on a certain day in July he would hold on his farm a "Grand Cattle Show and Fair free for everybody." This was a typical English cattle-show, and had little semblance to a fair. This was near Lexington. The following year another show of cattle was held similar to the first, and here was formed the first State Agricultural Society of Kentucky, which was the second in the United States. After holding two or three annual meetings this society disappeared, and but little if anything was done for the next 20 years, when again revived, prizes were offered for essays helpful to the farmer, and some eminent citizen, generally the Governor, delivered an address. Previous to this time, no ladies had attended the fairs, and it was thought a bold thing when a woman and her friend came under the escort of a gentleman to witness the showing of her own fat cattle. From this time the character of the fair changed, until it became a great holiday week with all its attendant mirth and gaiety, its courtesy and genuine Southern hospitality. Since the war the fair has changed greatly, and is now more a horse-show than a cattle-show. "The Oldest and Smallest Sect in the World," by Rev. Dr. Hurst, describes a small religious community now numbering about 150 souls, which has existed for nearly 3,000 years in the small city of Nablus in northern Palestine. Theodore Child contributes a richly illustrated article on "Holy Moscow," in which he describes many notable sights and curious customs, both holy and unholy. "London Mock Parliaments" describes the Society of Codgers, a semi-political debating club. The article has numerous illustrations. Then there is a very improbable story, "Joe Gilfillan;" and "The Religious Monument in France;" an instalment of "A Little Journey in the World;" "Editor's Drawer, etc." "Jupiter Lights," a very interesting serial by Miss Woolson, is concluded in this number. Harper Brothers, New York.

Various.

A JERSEYMAN'S JOTTINGS.

LAST week Axtell, the famous young trotting stallion, trotted a mile in 2:14, thus reducing his previous record by three-fourths of a second. The result was telegraphed all over the country and it was a very slow daily paper that did not print at least half a column about it. I doubt if the free advertising obtained by this telegraphing and publishing could be *bought* for $50,000. Who gets the benefit of it? Well, the gamblers who "back time" against Axtell or, *vice versa*, the crowds of people who go to see the horse trot, and the owners of Axtell or of other horses in his line of breeding, who are after big service fees. It's a great business, this trotting horse raising. I don't care to go into it: I am too slow; my horses would get ahead of me. The influence of the business is bad. Some farmers think they see a quick cut to fortune in breeding fast colts. It has always occurred to me that a man in order to raise trotters has to give up farming proper and become a regular horse jockey. If a man wants to do that, all right; but don't let him try to be a *farmer* and a fast horse breeder in the same year. Either the horse will rush the farm work so fast that it will fly all apart, or the work will so hamper the horse that he will be good for nothing.

Horse Racing is the favorite sport of thousands of Americans. What is there so demoralizing about it? The dullest man cannot help admiring the courage and almost human intelligence displayed by the first-class trotting or running horse. In the performance of the animal itself, there is everything to admire and nothing to condemn. Where then does the harm come in? Why are thoughtful religious people so universally opposed to horse racing? The railroad upon which I travel when I go to the city runs to one of the fashionable race-courses. Every night I come home from the city I pass through a crowd of men returning from the races. A look at the crowd will satisfy anybody there that is some thing absolutely soul-destroying at the race track. What faces! Greed, craft, despair, heartless exultation are all there. It is the most desperate, absolutely demoralizing crowd that one can imagine. The professional gambler with his cold, cruel face, walks with the totally depraved "tough." We feel instinctively that they are both armed ready to commit murder on the smallest provocation. Here is the boy learning lessons in vice and crime, that he never can rub out of his mind. Here is the trusted clerk desperate and haggard. He has lost the money he took without permission from his employer.

It is only a matter of days and hours now before his crime must be made known, and his good name blasted forever. And so the crowd rushes by to the ferry, some are cursing frightfully, others shout with glee, others rush past with the silence of desperation. Whenever I pass that crowd the utter wretchedness and cursedness of the whole thing come so strongly upon me that I feel that if I had a son who had been drawn into that fearful whirlpool, I should be tempted to pray that he might die before he reached the end of his course. I am not speaking of the rich people who enjoy the sport safely, never losing enough to render them desperate. They perhaps feel that they may safely enjoy the races, though I cannot understood how any fountain that pours out such a stream as that I have often spoken of, can help soiling all who come near it. Racing without gambling seems impossible. Those who take up the handling or driving of trotters must expect two things:—1. The money they obtain is essentially gambler's money. The trotter creates no property. He merely facilitates the passage of money, in the form of bets, from one man to another. 2. The racing horse practically creates a place for gamblers and other vicious characters to ply their demoralizing games.

Some farmers may like to be in such a business. For my part, I prefer something a little more in the line with my ideas of religion, even if it is a little slower.

A walking record is something I would like to see worked up. I would like to go to see the horse that can break the walking record. Why not do away with trotting at our fairs and encourage fast walking matches instead. The farmer's pace is the walk. If one horse can be so bred or trained that he can walk a mile in one minute less time than another horse can, that increased speed is worth money. Some of the breeders of heavy draft horses ought to start this matter. I can't think of any way in which they can obtain so much fame and business. The trotting and running horse folks have everything their own way in the matter of records. For one good farmer that is interested in knowing that Axtell trotted in 2:14, there would be five glad to know that Bob and Frank hauled 3,000 pounds a mile in 10 minutes at a fair walk. The breeders of Shire horses claim that their animals are superior walkers. Let them come to the front with walking records—with or without loads. Let the thing be persistently followed up and they would soon see a great interest taken in it, and the result would be in every way healthful. Our fair managers ought to take this matter in hand. It is well worth pushing.

A corn-cutter.—The RURAL prints a note from a man who made a cutter out of a hoe. I have tried it and like it well. A sickle is a poor thing to cut corn with; you can't strike or cut in the right direction. Most of the cutters sold have the same fault. This idea of the hoe ought to give manufacturers a hint about a new tool for this work. The hoe must be ground sharp; by the way, as far as that goes, hoes should be sharp all the time anyway.

CATALOGUES, ETC., RECEIVED.

RUBBER ROOFING.—Circulars from the Indiana Paint and Roofing Company, 42 West Broadway, New York. Anybody can make a roof of this material and it will last. It is just the thing for barns, sheds, poultry-buildings, etc., etc. The "slate paint" made by the same house will stop leaks in any roof. It will pay you to send for this circular. Surely you have some roof-space on your farm that will look and act better for a coating of this material.

GARDINER'S IRON FARM AND ROAD WAGON.—Circular from the Gardiner Iron Wagon & Manufacturing Company, Mullica Hill, New Jersey. This circular gives 28 reasons why this wagon is the "best in the world." It is a "low-down wagon on high wheels;" that is one feature that commends itself to farmers. The circular is well worth examining.

THE GARRET FENCE MACHINE, manufactured by S. H. Garrett, Mansfield, Ohio. This machine is simple and durable. Write for particulars.

JAMES M. THORBURN & CO., 15 JOHN STREET, N. Y.—An illustrated catalogue of bulbs and flowering roots, such as hyacinths, tulips, anemones, crown imperials, arums, crocuses, cyclamens, gladioluses, grape hyacinths, ixias, lilies, narcissuses, snowdrops, ranunculuses, scillas—comprehensive, well-selected lists of all. Among hardy seeds for autumn sowing, we have an excellent assortment of the best species and varieties.

THE EFFECT OF DIFFERENT RATIONS ON FATTENING LAMBS.—Bulletin No. 8 from Cornell University, Ithaca, N. Y. In this pamphlet, Professors Roberts and Wing give the results of a continuation of their experiments with feeding for fat and for lean. There is not much that is new in this story. The lambs were coarse-wool grades, Shropshire or South Down. They were better suited for experiment purposes than for profitable feeding.

THE RATION FED.

One lot was fed what may be called a carbonaceous ration. The lambs were given all the Timothy hay and whole corn they would readily eat, and in addition about a half pound of roots each per day. Turnips were fed as long as the supply lasted; after that mangels were used.

Another lot was fed a nitrogenous ration, although it was not so excessively rich in nitrogen as that used by some experimenters in trials of this kind. The grain ration was made up of two parts wheat bran and one part cotton-seed meal. A pound per day per lamb of this mixture was fed at first; afterward it was somewhat increased or diminished, as the needs of the case required, the object being to feed about all that would be readily eaten. This lot also received clover hay, instead of Timothy, and roots.

Still another lot was fed an intermediate ration. The grain part was composed of three parts corn and one part each of wheat bran and cotton-seed meal. It was eaten in about the same quantity as the second lot. Timothy hay was used for this lot and roots were fed as in each of the others.

A fourth lot were fed the same as the third, except that they received no roots at all.

The bulletin presents an elaborate statement of the cost of food, gain in flesh and the weight of different parts of the body. This is not given here for the reason that the result is practically the same as that arrived at in the previous experiments which we have given in detail. The experimenters conclude, as the pith of all their feeding experiments:

"That corn, as an exclusive grain ration, does not give the best results, either in amount, quality or economy of production, when fed to growing or fattening animals.

That the amount of water drank (especially in the case of our lambs) is a pretty certain indication of the rate of gain.

That the production of wool is very greatly dependent upon the nitrogen in the ration."

The bulletin concludes with the following remarkable statement:

"Since a large portion of the arable land in the State of New York is now cultivated at a possible loss or at a very small profit, and since the reason for this is largely want of plant food in the soil; therefore, the value of the voidings of animals and the character of the plants raised on the farm, must necessarily receive our most careful consideration."

A table is introduced to show the manurial value of the different rations when fed to sheep. It is claimed that the "nitrogenous ration"—the one in which bran and cotton-seed meal are used—is three times as valuable for manure as the "carbonaceous ration" where corn is the only grain used.

KANSAS CROPS AND WEATHER.—The statement of the State Board of Agriculture for July is interesting—not by reason of its treatment of the subjects with which it is supposed to deal, but because of other matters. We don't care much now how the crops looked last July, and the weather at that time is also of little importance just at present. Secretary Mohler has contributed a sensible article on agricultural statistics, that gives this bulletin considerable value. It seems that some Kansas farmers refuse to give agricultural statistics, as they say their figures will only be used to the detriment of farmers. In fact, it seems to be pretty generally believed by a large class of farmers that all the figures or crop information they give is seized upon by speculators and crop gamblers to manipulate prices in their own interests. Secretary Mohler argues against this view and gives reasons why reliable statistics will benefit Kansas. He says:

"Grain gamblers connected with the boards of trade in our large cities have men in their employ traveling continually during the growing season, in every part of the country, gathering the facts in regard to the acreage and yield of wheat and corn per acre, and other crops; and it is surprising how near they get at the exact facts long in advance of the time the assessors' returns reach this office. These men are experts at the business, and do their work thoroughly. These grain speculators are not, therefore, in any way dependent upon the returns made by the assessors to this Board for carrying on their gambling operations, but are wholly independent of them. Now if the people had no means of collecting these statistics, compiling and giving them to the public, there is no telling what these unscrupulous men would do. The farmers would then be at their mercy. They could withhold the truth from them and practice their art with direful effect upon the farming world. The farmers would be in darkness and the grain gamblers in the light. Ignorance can never cope with intelligence in any kind of warfare."

He always gives this advice, which will apply to 36 other States besides Kansas:—In selecting assessors the best man in the township should be taken for the work—one not only competent but pains-taking, and ambitious to do his work well. Better work is badly needed, and assessors at their annual meeting for fixing a basis of valuation, should discuss this matter and pass a resolution pledging themselves to do thorough and complete work, including, of course, agricultural statistical work, and the county clerk of each county in the State should urge upon the assessors the importance of such work.

Law.

"Every Man is presumed to know the Law. Nine-tenths of all Litigation arises from Ignorance of Law."

LEGAL FRAUDS IN SALES.

T. M. S., Armstrong County, Pa.—A sold B a horse blind in one eye, the supposition being that the animal was sound in all respects. A said nothing about the horse's eye-sight, and B did not notice the defect. Can B, after discovering it, compel A to take the animal back or, on his refusal to do so, recover damages?

ANS.—No. B was not legally bound to disclose the fact that the horse was blind; he had only to refrain from doing anything to conceal the defect or to prevent the purchaser from discovering it. It has even been held that one who buys a horse that is blind even in both eyes, after having had an opportunity for examination, is not protected by a general warranty of soundness; but, on the other hand, if the defect is one that cannot be discovered by reasonable diligence and care, the law requires the seller, if he is aware of it, to point it out. The ancient adage "*Caveat emptor*"—Let the buyer beware,"—is applicable in all such cases. The law affords every reasonable protection against fraud in dealing, but it does not go to the romantic length of giving an indemnity against the consequences of ignorance, folly or carelessness, where ordinary and accessible means of information have been neglected. If the parties meet on equal terms and have the same means of information, and if nothing is done to divert attention or conceal defects, there can be no fraud in law; for though the goods may be defective, the vendor is under no legal obligation to point out defects which any one may see if he will look for them, and though the seller may say the goods are better and more valuable than they really are, even then the buyer is supposed to rely on his own skill and judgment. If he has a full and fair opportunity to do so, he must look out for himself, or suffer the consequence of his own imprudence. If the vendor, however, covers up or conceals defects, or if he misleads the buyer or puts him off his guard in order that he may not discover them, or even if he fails to point out defects,—such as the habits or non-corporeal characteristics of an animal, for example—which the buyer has no means of discovering for himself, he is guilty of a fraud in law, which renders the sale voidable. This rule relates to a multitude of matters of every-day occurrence.

THE SALE OF HOME-PRODUCED WINE AND CIDER.

H. B. H., Yates County, N. Y.—Has the producer of native wines and cider, made by himself, or his employes, from the grapes or apples of his own production, the right to sell the same by the barrel or gallon, without a license?

ANS.—Section 3,246 of the United States Revised Statutes provides that no special tax shall be imposed on vintners who sell wine of their own growth at the place where it was made, or at the general business office of the manufacturer. No United States license, therefore, is needed to sell under the circumstances mentioned by our correspondent. But an excise license is needed under the New York State law in order to sell wine in quantities of less than five gallons, or to sell it in any quantity to be consumed on the premises. No license, however, is required for the sale of home-produced cider.

COMPENSATION FOR SERVICES TO A DECEASED PARENT.

I. M., Herkimer County, N. Y.—If a parent dies without making a will, and one of the heirs performs all the necessary services during his parent's sickness, can he recover the value of such services out of his dead parent's estate over and above the share of it coming to him legally?

ANS.—When an adult child resides with and performs services for a parent, an understanding between them for recompense may be shown. Where the parent was sick and infirm for a long time and where the child's services were indispensable or very important, a mutual understanding that the child should be paid is often inferred from the circumstances, and compensation is allowed out of the deceased parent's estate upon the usual footing of creditors.

Trees, Seeds and Plants.

J. M. THORBURN & CO.,
15 JOHN STREET,
NEW YORK,
BEG TO ANNOUNCE THAT THEIR DESCRIPTIVE PRICED
CATALOGUE OF

Horticultural.

The Newer Varieties of the Blackberry.

HOW THEY ARE REGARDED BY PROMINENT AUTHORITIES.

Communications from President T. T. Lyon, M. Crawford, E. Williams, P. M. Augur, et al.

Varieties Growing at the Rural Grounds, With

PHOTOGRAPHIC ILLUSTRATIONS.

FROM PRESIDENT T. T. LYON.

EARLY KING BLACKBERRY.—I have not yet been able to make a satisfactory test of this variety.

THE MINNEWASKI proves hardy enough to withstand our lake-shore climate, and promises well as to productiveness; but another season, at least, will be requisite properly to determine its status in this most essential particular.

ERIE is claimed by many growers to be identical with the Lawton. There surely is occasion for such assumption; but, with me, the Erie has decidedly more of the trailing or spreading habit of the dewberry, although it is a very vigorous, sturdy grower, and possesses even stronger and more prehensile spines. The fruit also is more rounded and regular, and less elongated. With me another year is needed to test its value thoroughly, although my experience so far is decidedly in its favor.

SNYDER lacks productiveness as compared with the Kittatinny, Early Wilson or Lawton, and the fruit, although of high quality, is decidedly lacking in size. Its popularity is mainly due to its great hardiness.

TAYLOR, after a good many years' trial, has proven, with me, quite as hardy as Snyder. It is a more spreading grower, with peculiar, yellowish-green canes. It requires a season or two longer than Snyder to come fully into bearing; but when it "gets fairly down to business," it is even superior to the former in productiveness; while the fruit is larger, more elongated, later, and quite as high in quality.

WILSON JUNIOR is, in all respects, very much like its alleged parent—the Early Wilson—although there are slight differences. The former, with me, ripens two or three days in advance of its parent.

THE LUCRETIA DEWBERRY is very productive, and although scarcely as hardy, when fully exposed, as many of the blackberries, its trailing habit usually so far protects it, in winter, that it rarely suffers from low temperature. The fruit corresponds, in size, with the largest blackberries; while it ripens very nearly with the earliest blackcaps, which circumstance doubtless renders it all the more desirable. The fruit is borne so near the ground that a mulch is needed to keep it clean, quite as much as in the case of strawberries. Everything considered, I regard it rather as a fruit for home or family use than as desirable for the market.

WACHUSETT is a variety I have tried to make something of for a number of years; but it has, with me, proved utterly worthless, and I have consigned it to the rejected list, along with numerous other thornless varieties. Thorns and fruit, in my experience so far, seem almost, if not quite, inseparably connected.

AGAWAM has been in my collection nearly or quite 15 years, and I regard it as of very decided value. The fruit is of fine size and excellent flavor; and the plant a strong grower, and sufficiently hardy for the lake shore; although, doubtless, somewhat less hardy than Snyder or Taylor.

EARLY HARVEST was unfortunate in its introduction to the public. My first trial of it was with plants received direct from the introducer. These proved very tender, killing to the snow-line each winter. Not suspecting their genuineness, under the circumstances, I have frequently and strongly condemned it as valueless at the North. More recently this proved to have been the Brunton. The genuine Early Harvest has been grown largely, for several years, at Benton Harbor, 20 miles south of this place, and has proved to be not only hardy, but one of the most profitable varieties grown in that region. My own experience with the genuine, is as yet quite limited.

South Haven, Mich.

FROM SECRETARY M. CRAWFORD.

Early King, Minnewaski and Wachusett have not fruited here. The Wilson Junior and Early Harvest are by far too tender for this climate.

AGAWAM is the most satisfactory variety I ever raised. It is perfectly hardy here, quite early, wonderfully productive, of good quality, a little larger than the Snyder and smaller than the Taylor. The genuine is hard to get.

SNYDER is usually hardy, and with high culture and close pruning the size is medium. It ripens between the Agawam and Taylor. The quality is only moderately good and its habit of turning red after being picked, detracts from its value.

TAYLOR is nearly as hardy as the Snyder, fully as productive, later in ripening, of larger size and far better quality.

ERIE originated in this county in a neglected vineyard belonging to L. B. Pierce, the well-known horticultural writer. It is one of 50 or more that came up at the foot of the posts where the robins carried the berries from a patch of the Lawton that grew near by. After a time the posts rotted off at the ground and fell over, carrying the vines down with them. This gave the blackberries an opportunity which they promptly improved. This variety occupied about a rod of ground, which Mr. Pierce assured me yielded from 30 to 35 quarts at a picking three times a week; and it bears a long time. On the strength of this report I paid $50 for the entire stock, and a few weeks later, I sold it to a party in New Jersey for $100. He grew it one year, and divided the stock into ten equal shares, which he offered to nursery-men at $500 each, reserving one for himself. Each purchaser increased his stock as much as possible the next year, after which it was put upon the market. It is very much like the Lawton, but I do not think it is that variety. It has all the desirable qualities, except hardiness, and will doubtless be a satisfactory variety where the climate is mild enough for it.

THE LUCRETIA is a very desirable variety, if one can put up with its habit of running all over the ground like a water-melon vine. It is rarely winter-killed, either because it is so hardy or from its habit of lying on the ground where it is covered with snow much of the time. The berry is even larger than the Lawton, and of pretty good quality. Hardiness is the important point with blackberries in this climate. Without this, all other good qualities go for nothing. The following are hardy in the order named, and are all that I *know* to be reliable: Agawam, Stone's Hardy, Snyder and Taylor.

Summit County, O.

FROM CONNECTICUT STATE POMOLOGIST, P. M. AUGUR.

EARLY HARVEST is very early, choice and good; not large. It is too tender to be trusted north of New York City. Snyder and Taylor are prolific and hardy, of good quality, and can be depended on.

MINNEWASKI is large, productive, hardy and good.

ERIE I regard as distinct from the Lawton, and better. The canes are hardy with us. It is not quite as productive as Snyder, but the fruit is much better, being large, jet-black, with a mild blackberry flavor. It is our favorite for home use.

WILSON JUNIOR, like the old Wilson, is not reliable with us; the fruit is large, fine and excellent.

THE LUCRETIA DEWBERRY, for those who want a trailing berry, is what it purports to be—hardy and productive. For one variety and under all circumstances I would select

MINNEWASKI BLACKBERRY. From Nature. See page 606. Fig. 228.

the Snyder; for two, the Snyder and Erie; but I prize the Minnewaski nearly as highly.

Middlesex County, Conn.

FROM SECRETARY E. WILLIAMS.

EARLY CLUSTER.—Of this I have a few plants which have always proven hardy and productive. It is also early, but how it compares in this respect with others I cannot say. The berries are about the size of Snyder as I have seen them elsewhere, and the quality is good when I pick them myself and I think this will apply to all others.

THE ERIE, to all intents and purposes, differs very little from the New Rochelle, save in earliness. It is, I think, a week or 10 days earlier than the Rochelle and fully as deceptive in appearing ripe before it really is.

MINNEWASKI has not yet fruited with me.

THE SNYDER is hardy and immensely productive. Its small size is the chief objection to it; but a gentleman near Morristown, who has several kinds considers it the best of all, if grown on very rich ground and severely pruned. With this treatment he gets it of a very satisfactory size, much larger than I have seen it elsewhere.

THE KITTATINNY is the best of all I have tried or seen; it is large, productive and excellent in quality; but if I eat the berries I must pick them myself. From a couple of stray plants a few days ago I picked a quart that were delicious, reminding me of old times. These plants stood in grass and had not been pruned nor had they received the least bit of attention; but it will not do to say of any blackberry I know of that it is ripe when black. The Dorchester comes nearer filling the bill in this particular than any I have seen. As ordinarily picked I invariably pass this fruit till canned or cooked, as hard, sour blackberries, even if smothered in cream and sugar, are repugnant to my taste. If we could get a blackberry that was really sweet and good when black, it would be a desirable acquisition, and my affection for this fruit would be stronger.

Montclair, N. J.

FROM E. C. BRINSER.

THE EARLY HARVEST is the earliest of blackberries. It is very productive, of rather small size but of good quality and fine appearance and it sells very well when customers get to know it.

WILSON JUNIOR seems to me to be a failure as the vine is a very poor grower and not hardy enough. The fruit is large and abundant if the vine doesn't freeze back; but it is of poor quality. I have little faith in it.

ERIE is much better in growth and quality of berry and has done fairly well on year-old plants.

SNYDER is very productive and of good quality; but it bears so heavily that the fruit is of rather small size compared to the Kittatinny or Erie.

Schuylkill County, Pa.

FROM T. H. HOSKINS, M. D.

I have only the Snyder and Sable Queen, both of which do well. The latter is the larger and better of the two. Hard winters kill them both to the snow-line unless laid down.

Newport, Vt.

FROM MRS. A. L. JACK.

I intended to speak a good word for the Lucretia for it has done well with us this year, though we did not let it go at its own sweet will, but trained it on two wires along the row. The berries were plentiful and black. We picked them, but, sad to relate, there was an after-taste of bitterness in the mouth as one feels after eating horehound drops, and they will not sell the second time, though large and plump. "Leave them till they are fully ripe," some say; we have tried it, but they are treacherous, and we do not know when they *are* at that stage. If one happens to get as far advanced as to be eatable only the mangled remains can be discovered, for the birds find them first. No, the Lucretia is not all it was boomed to be.

Quebec, Canada.

FROM PETER COLBY.

On account of plenty of wet weather, our blackberries—the Wachusett—are very large and the bushes are loaded. They can be picked more easily than others on account of the very few thorns they have and these are straight, so that they do not cling to the clothing, and the vines are perfectly hardy, as we live in sight of Wachusett Mountain where this variety originated. We think the berries sweeter than others and will have over 20 bushels on our piece. I shall try the Agawam another year, but I dread the thorns.

We ship to Boston. Prices this year so far eight and 10 cents per quart. We make a clear profit of $2.00 and $2.70 per bushel. Does this pay? Yes, better than anything else we can raise. We want three or four quarts per day for home use and it is about as easy to raise one-quarter or one-half an acre and ship the surplus, and so get our pay for cultivating them.

Stafford County, N. H.

Notes from the Rural Grounds.

THE NEWER BLACKBERRIES.

With photographic illustrations of Minnewaski, Erie, Early King, Bagnard and Gaynor.

EARLY KING.—Several plants were received from J. T. Lovett of Little Silver, N J., and planted April 21, 1888. It is said to be from Missouri, and the claim is made that it is remarkably hardy having endured 36 degrees below zero; that it ripens earlier than Early Harvest; that it is larger and of delicious sweetness. It began to ripen here one week *after* Early Harvest, which is the earliest blackberry we have ever tried. The berries are of better quality though not so regular as those of Lawton. They are better in quality than Early Harvest—not so good as Kittatinny. The canes are more thorny than those of Kittatinny. The berries, as shown at Fig. 230, as photographed from nature, are of medium size. It is rather earlier than Lucretia. Conclusions should not be drawn from a single year's trial. The canes have made a vigorous growth.

ERIE BLACKBERRY. From Nature. Fig. 229

MINNEWASKI.—The first plants were received from J. T. Lovett in April of 1887, as Mr. A. J. Caywood, the originator, declined to furnish them, as he objected to any trial of this variety by the R. N.-Y. It was first illustrated in the R. N.-Y. (from specimens sent to the office by Mr. Caywood) December 19, 1885, page 869.

It ripens with the Kittatinny; the berries and drupelets average somewhat larger. The quality is not quite so sweet. The canes and spines are similar. Nothing further can be said of its hardiness except that the canes have never been injured, though the winters have been mild since the plants were set. We regard the Minnewaski for this locality as only second to Kittatinny with a probability that it is a hardier variety. The illustration, from nature, is shown on the first page.

BAGNARD.—Received from E. F. Richman, Muscatine, Iowa, March 14, 1887. He writes as follows:

"It originated on the farm of L. Bagnard near Muscatine, and is undoubtedly from the seed of Snyder. This is a trying climate. So far the Bagnard has shown no signs of injury from cold though growing in an exposed situation."

It ripens here nearly with Kittatinny. The berries are not so large though larger than those of Taylor. Quality not so good as Minnewaski. The plants are very prolific and thus far perfectly hardy. Fig. 232 shows a single berry of the average size.

BANGOR.—Received from Chase Bros., Rochester, N. Y., April 1886. Excessively productive. The bushes are at this time (Sept. 1st) a mass of berries of small size but few of which are ripening. The quality is insipid. It is impossible for any blackberry to mature such an immense quantity of fruit. The canes are hardy.

ERIE.—It is claimed by the introducer for this variety that it is earlier than Wilson Jr. and combines more points of excellence than any other blackberry known. Several well-known authorities state that it is the Lawton. It seems to the writer that the canes are hardier and that the berries while about the same in length are thicker in diameter. It ripens this season with Kittatinny. Fig. 229 shows a photo-engraving of an average cluster of berries.

TOPSY.—It ripens with Kittatinny. The canes are so beset with thorns that this variety is not desirable even though it possessed distinctive merits which it does not, in so far as has been observed.

AGAWAM. This was illustrated and described in the R N-Y. of August 24.

BONANZA.—The berries are not quite as large as those of Kittatinny with which it ripens. Quality not quite so good.

GAYNOR.—From Morris, Stone and Wellington, Welland, Ont., Canada, spring of 1886. The quality is much that of Kittatinny, though the berries do not average so large. Very prolific and hardy. See Fig. 231.

FAIRFAX DEWBERRY.—C. A. Uber, Falls Church, Va. Not so prolific as Lucretia; berries smaller.

EARLY HARVEST is the earliest of the blackberries tried here. It is tender to the extent that it bears a full crop not oftener than once in four years. The berries are rather small, the drupelets are small but of such uniform size that every berry is almost a facsimile of every other berry. Firm and handsome, but rather insipid.

LUCRETIA DEWBERRY.—This has been allowed a place here ever since May of 1885. The berries are large—larger than those of Lawton—of fair quality, ripening before the Kittatinny. If allowed to run over the ground naturally, one has to stoop low to pick them. The difficulty is increased by the thorny, entangled vines. If obliged to depend upon the Lucretia for our blackberries or go without, we should prefer the latter.

CUT-LEAVED, EVERGREEN OR PARSLEY-LEAVED BLACKBERRY.—This was received from J. M. Ogle, Puyallup, Washington Territory, in the spring of 1886. The next year it was extensively advertised as a marvel of productiveness, etc. It is not quite hardy here, but this season it bears a full crop. The leaves are glossy and fernlike. The numerous thorns of the slender, pliant stems incline sharply downward, as sharp and rigid as needles. The berries are a glossy, jet black, sweet, small to medium in size—the drupelets large with large seeds. It is of interest as a curiosity, not without some value either for ornament or, one year in five, for its fruit. It is a variety of the European blackberry—Rubus fruticosus.

An excellent illustration of the spray and fruit appeared in the R. N.-Y. of February 6, 1886.

SMALL FRUIT REPORT.

As I was reading the reports of different varieties of strawberries sent in from different points, I felt amused at their conflicting nature and thought I might as well add mine, which will, no doubt, be just as conflicting. Our season was one of incessant rains and floods. The extremely wet weather brought out the berries to their utmost size: but, as a natural consequence, they are lacking in quality. I have land in two tracts not a mile apart, and the nature of the soil differs so greatly that strawberries at home in the one soil nearly fail in the other. The one is a loose loam, while the other is a very solid, tenacious loam. In the former the Sharpless and other varieties of the same nature are at home.

STRAWBERRIES.

JESSIE has fruited with me twice. It is a good grower; foliage clean; fruit of high quality, firm, of large size, early and of even color and the vine is as productive as most sorts. This year, however, it was severely damaged by the great floods of rain in the early season, but it improved wonderfully from the middle to the latter part of the season.

BUBACH is, I believe, all that is claimed for it. None is better in foliage. The fruit is of immense size; but only moderately firm; it colors evenly, but is medium in quality to my taste. The vine is very productive.

MONMOUTH is the earliest large berry I have yet tested. It is a few days earlier than the Crescent or May King. It averaged as large in size as Cumberland and yielded twice as much. It is of good shape and quality, very firm and a very strong grower.

MAY KING has done remarkably well. The fruit if properly grown is of fair size and of such fine flavor that I shall continue to grow it. It is a little pale in color, but so very firm and good that purchasers who know it like it very much. It is my favorite eating berry in the patch on account of its peculiar flavor.

GANDY'S PRIZE is the latest variety I have. It is a strong and healthy grower. The fruit is of fine form and large size, firm and of good quality, but with me the vine is not as productive as I desire, but as the fruit ripens so late in the season it is valuable on that account.

MANCHESTER is very productive and valuable for preserving, but so subject to rust and blight that I must drop it.

BURT I have not fruited, but find it a wonderful grower.

CUMBERLAND, which is one of our standbyes, has partially failed with me this year. I think the wet weather is the cause.

CRESCENT I will drop from my list after two years' trial. The fruit is too small and sour.

SHARPLESS is more to me (or has been till now) than any other variety. It bears so well and the fruit is of such size and quality that it sells for more money than any other kind. If I were forced to grow but one variety, it would be the Sharpless, but I am glad we have good varieties that are earlier. Of Mammoth Seedling, Crimson Cluster, Belmont, Jewell and Charles Downing I need say nothing except that I shall drop them.

RASPBERRIES.

Of raspberries we had a fair crop.

SOUHEGAN is the earliest, but the fruit is not so large or good as Gregg. I find its fruit about gone when the Gregg comes in. I have now planted the Ohio to fill the gap.

GREGG is late, but when the climate is not too cold it is more profitable than other sorts on account of its size, quality, firmness and productiveness.

HILBORN is a few days later than Souhegan, but of a larger size, a stronger grower and more productive. It has a finer appearance than any berry I know.

NEMAHA is the strongest grower of all the black-caps I know. The fruit is even larger than the Gregg, and about the same in other respects. It is said to be entirely hardy. Should this prove true it will be very valuable.

CUTHBERT is the leading red here.

HANSELL is early but not so large or so good.

SHAFFER'S is a rank grower and very productive; fruit large and very good, but too soft for shipment. E. C. BRINSER.

Dauphin County, Pa.

Farm Topics.

THOUGHTS AND FIGURES ON HAYING.

PROFESSOR I. P. ROBERTS.

IN this locality it has required careful planning, prompt execution, and first-class implements to secure the hay crop in good order. Failures and successes may now be noted that we may be wiser in the future. Those who cut their clover hay *very* early, had little difficulty in curing it. We cut one small field on June 10, and to-day—August 5—are cutting a heavy second crop—1.68 ton per acre. This method of cutting the first crop *very* early, before the clover has lodged, and the second one in August, before the cool, damp nights come on, I propose to follow in the future, now that the land is fertile enough to bring the plants on rapidly. Field No. 2 was badly lodged, and was cut when a little over-ripe, as it rained about every day when it was in the right condition; but hay-caps, energy and two continuous days of fair weather enabled us to bring it to the barn in good condition. I should have cut this field June 5th to 10th. Better a little over or under ripe than spoiled hay. Field No. 3—Timothy, with a little clover—contained 3.85 acres, and was cut with a Eureka Mower in two hours and 10 minutes; raked in one hour and 30 minutes, and bunched by one man in 10 hours. The time of loading—two pitchers—was 18 minutes; the time of unloading, 10 minutes per load. Four men were in the barn—two to mow away, one to handle the sling and one the team. There were 11 loads of well-cured hay, weighing 12 tons 190 pounds. This Timothy was cut July 9th and hauled the 11th and 12th. The rain caught a few shocks, but most of them were covered with hay-caps.

HAY FIELD——DR.

Man, team and machine, two hours and 10 minutes, at 50 cents per hour....	$1 09
Raking, one hour and 30 minutes, at 20 cents per hour.....	30
Bunching, 10 hours, at 15 cents per hour	1 50
Pitching 11 loads, three men, 18 minutes, 10 hours.....	1.50
Unloading, four men, 10 minutes, 11 loads, at 15 cents per hour..	1.10
Second raking, one hour and 30 minutes, at 20 cents per hour.....	30
Extra time for pitching rakings.....	15
Capping.....	25
Five hours extra work on uncapped hay	75
Teams, 10 hours, including time to and from field, etc.....	2.00
Four hours consumed by teamster to and from field.....	60
Add 10 per cent. loss for sundry lost time between loads, changing to other work.....	95
Total.....	$10.49
Cost per ton.....	.87

I believe the large field of Timothy was secured at a less cost per ton, as the field was much longer and there was no rain to hinder.

The hay referred to above from the small field was bunched when quite green, and went into the barn with that "silky" feel which good judges of hay prize so much. I would quite as soon have a shower on hay as a few hours too much sun. Since seeing my neighbors operate a hay-loader and tedder this wet season, I am strengthened in my opinion that there is little place on a well-managed small farm for either; and I am very doubtful whether they are a financial success, except under unusual conditions.

Seeing the difficulties and the frequently increased cost of gathering the grain and hay (too often poor on account of the heavy rainfall), I am led to the following conclusions: If farming is to be profitable, there must be a large yield per acre. To get this large yield, there must be grown, not only the better varieties, but the best for the conditions present. The Lord never planted cat-tails on a dry hill-side, but I have known farmers to try to raise celery in gravelly sand. The plant, to do its best, must have an abundance of food and water, but not too much. We, as farmers, are here to regulate these things. And the Lord said: "I give you dominion." The crop must not only be raised, but also secured at the minimum of cost per ton or bushel. Machinery and tools must be as simple as possible, strong, durable, and, above all, effectual. There are good potato-diggers and ditching-machines; yet 99 per cent. of all the ditches and potatoes are dug by hand-labor, simply because, under most conditions, a dollar is more effective when expended for hand-labor than for machinery. The mower and binder must, under good conditions, cut an acre and a half per hour. This implies a team able to draw them continuously at their most effective speed, and, above all, a man—dominion!

It will be noticed above that I have charged $5 a day for sharp knives, a sharp man and a good team; yet the expense was only 28 cents per acre, because the means used were well-adapted to the purpose, and, hence, effective.

Three-fourths of a ton of hay and daisies; 16 bushels of wheat and cheat; 28 bushels of oats and a ton of Canada Thistles per acre; $80 for a horse; $1 50 for a sheep (I saw yearlings sell in Buffalo last spring for 50 cents); 165 pounds of butter per cow—these are the averages. Who takes the hindmost?

34 bushels of wheat, and straw.....	$40.00
Rent, labor and plant food.	20.00
Profit, 100 per cent.	
Three tons of hay (one or two cuttings),	$30.00
Rent, plant food and labor.....	15.00
Profit, 100 per cent.	
75 bushels oats and straw.....	$36.00
Rent, plant food and labor.....	18.00
Profit, 100 per cent.	
Grade French, or Clyde.....	$200 00
Cost.....	80.00
Profit, 150 per cent.	
750 pounds milk, or 300 pounds butter,	$75.00 to $100.00
Calf and skimmed milk.	
Profit, ——. Profit, ——.	
100 early lambs.....	$600.00
Profit, ——! Profit, ——! Profit, ——!	
100 yearlings in Buffalo.....	$50.00
Loss! *Loss!* Loss! LOSS!	

Somewhere, my reader, in the above array of figures, you will find your own case. Look in the palm of your callous, nut-brown hand and see if in those well-marked lines you see an L or a P.

Cornell University, Ithaca, N. Y.

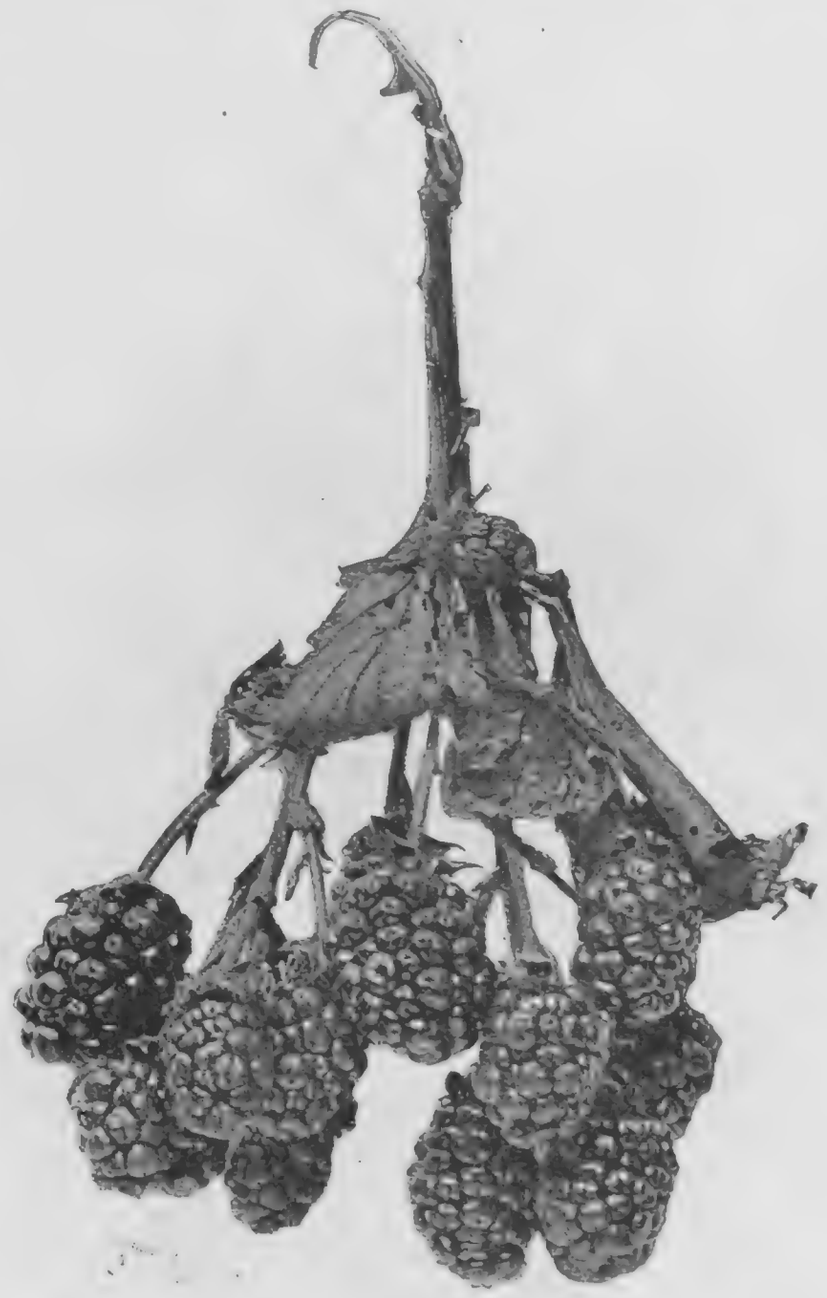
WHY MANY FARMERS DO NOT SUCCEED.

IN many sections of the country we meet with a great many farmers who are always complaining about hard times. They practice what they believe to be the strictest economy; they work hard enough, but the money does not pour in upon them in a very large stream. Really it does not run into their pockets in any stream at all; it just reaches them in far-between meager drops. A few other farmers owning no more or better land, and who work no harder have money enough. Why is it that one has golden eagles jingling in his pocket and the other only silver dollars?

The answer is apparent enough to any one who spends any thought upon the subject. It is expressed in the single word "*management.*" When a man owning a farm begins to groan about "hard times," and complain that he has no money, it would be the best thing for him to do to stop and ask himself: Why do I get no money? Why are the times hard? Nearly all sorts of farm produce bring good prices. Bear in mind the fact that you cannot get something for nothing. If you have nothing to sell, how do you expect; how can you hope to receive any money? Look the matter fairly in the face. You have a hundred acres of land; you raise two or three acres of wheat, half a dozen acres of oats, some corn, say three or four acres; you cut the grass from 20 acres of meadow; you keep a work team and a carriage horse, a dozen cows, three or four hogs and a few poultry. You eat the wheat, feed the grain and hay to the horses and cows, hogs and poultry; you eat the hogs and eggs and all you have is what is left from the dividends of the cheese and butter factories after having paid one man for hauling the milk, another for making the cheese or butter and other incidental expenses, such as cartage to the railroads, freights, drayage, commissions, etc. All you have sold from your farm has been the milk, and the income from that has been whittled down and down until the price that reaches you only a little more than pays taxes and a few other expenses which are absolutely necessary, and if you or your family wish to take a little recreation by attending the State fair or spending a few days in the city there is no balance in bank to foot the bill.

Well, who is to be blamed? Haven't you obtained all you have earned? Cannot you make a review of your old "run-in-the-rut" way of farming, and do something that will pay better? Can't you raise some crops that will give you a better margin of profit than corn and oats? Suppose that you leave out a part of the oats and corn and raise more products of the garden—say onions, cabbage, squash, or some other, crop that can be sold for $100 to $200 in cash. And then after you have got the cash, make it worth more to you than it has been in the past. Not having had the ready cash, I know how you have managed. You have been accustomed to go to your country store, buy whatever was necessary, have it charged, pay enormous profits, and your money has been of but little use. The better way is to send away to some wholesale dealer and buy enough at a time to last six months or a year, and you will be surprised at the saving of money accomplished. I have practiced this sort of economy for several years and I know how it works. Of course, there are some articles that I do not send away for, because I can buy them at home almost as cheap; but upon the groceries, dress goods, clothing and articles for use in the house, I think I save at least 25 per cent., and one-fourth of the store bill very often makes quite a difference in the spending money for a family's pleasure. Try it, good reader. Raise more products of the farm that will sell for cash, and then make your money buy more of what you want.

C. T. LEONARD.



EARLY KING BLACKBERRY. From Nature. See page 606. Fig. 230

Dairy Husbandry.

CLOVER AND CORN-FODDER VERSUS TIMOTHY.

PROFESSOR J. W. SANBORN.

Stover as yet a woeful waste in the West; its great value for feed; clover and stover from a given area far more valuable for feed than the Timothy therefrom; grasses, however, indispensable in a rotation; small cost of their production and handling; places of grass, clover and corn in a six years' rotation; beneficial effects of growing all; planting, harvesting, and feeding fodder corn; corn our most productive fodder crop; a combination of clover and stover excellent for beef or butter production; ensilage not yet the best means of utilizing corn for feed; clover, corn and Timothy excellent on a dairy farm.

THE following question is submitted: "Should a dairyman use Timothy as a part of his rotation? Will he not do better to so change his rotation as to have corn-fodder and clover in the place of Timothy?"

At present corn-fodder in the West is practically a waste product of corn-growing, and as such is made but of little use considering its great nutritive value. This, in view of the present developments of the West, has degenerated into a vital wrong, for the nutrition in an acre of corn-fodder is equal to or really exceeds the nutrition in the corn it bears. It needs no argument to show that a process that is half waste in crop growing opens a field for economy in a period distinguished by the wealth derived from former wastes. I have been radically opposed to any system of farming that results in such a waste, and so I organized, on the Missouri College farm, a system of rotation of crops that saved everything grown, but it was especially aimed to conserve the wasted corn-fodder or stover—let us call it stover. In this rotation clover held a conspicuous place and Timothy a smaller one than is usual. I do not, however, hold that the Timothy should be dropped out entirely, nor do I believe that it can be dropped out without loss, over most of this country.

I am a believer of the most pronounced type in a rotation which is in harmony with certain natural laws. I cannot see how the grasses can be dropped out of a rotation without injurious effects. The binding influences of grass roots, their influence in decreasing the leaching of the soil through the great amount of water evaporated through their leaves, the decrease of the washing of the surface soil, the accumulation of nitrogen in the soil, or at least the proven conservation of the nitrogen of the soil, the favorable influence of the great mass of roots left in the soil, and the fact that it affords the cheapest source, as I believe, of animal food when grown upon a favorable soil, would make the limited use of grass as a crop to me indispensable on the farm under ordinary conditions.

Touching the cost of Timothy or hay as compared with hoed crops, it must be borne in mind that grasses require the minimum of labor, now so troublesome a problem on the farm. The seed is cheap, and once seeded, a field is seeded for a few years, while the har-

vesting of grass—which alone is left—is phenomenally cheap compared with the cost of harvesting other crops. Again, Timothy yields more nearly as much as do the tillage crops than is generally supposed. A soil fitted for grass with available fertility enough to give good hoed or grain crops, would easily yield three tons of Timothy, or at least it does with me. The trouble is that we grow corn and grain and take the cream off of the soil, and then follow with grass. Three tons of hay would give 5,400 pounds of dry matter per acre. To furnish this amount of dry matter in green fodder-corn would require 13½ tons. Without collecting the data reported, I judge that 16 tons per acre are more than the average yield of the country. Now 16 tons of fodder-corn would give but 6,400 pounds of dry matter. Furthermore, the hay will be more completely eaten in the barn and will be more cheaply handled.

I do not wish to prove that grass should hold sway in dairy farming, for in my own practice Timothy occupies two years only in a six years' rotation, but I insists that its physical and chemical effects on the soil and its economy of growth should make it a welcome crop in a rotation and indeed retain for it an honored place. The reasons above assigned in a general way would appear stronger when reviewed in the light of critical detailed data drawn from the close work of investigators.

Having said this much in defense of Timothy, I will express my favorable opinion of corn-fodder and clover; in fact, I use in practice one year of clover and one year of corn-fodder for every two years of Timothy in the six years of rotation. I will get, it is my belief and within my knowledge, more nutrition in the two years of corn and clover than in the two years of Timothy, yet these increased amounts will be greater than they would have been had Timothy not been grown, and, on the other hand, the Timothy crop will be heavier than it would have been had not clover and corn been raised.

I take it for granted that the questioner makes a distinction between corn-fodder and fodder corn, and that in the use of the former term, stover, the husked corn plant, is meant, although fodder-corn is more often advocated for the dairy.

I am inclined to think—indeed I have to some extent practiced it—that I should plant my corn just a little—but not much—thicker than in ordinary field practice, and then harvest and feed it with the nearly perfected ears on it, allowing hogs to follow the cows and use any undigested corn that may have passed through the cows. This saves the great cost of harvesting and grinding corn, and in my opinion involves little waste.

By the phrase, "feed it with the nearly perfected ears on it," I do not by any means desire to convey the idea that I would harvest it before it had matured. I hold firmly to harvesting only after the plant food ceases to enter from the ground. When the crop has been planted more thickly than in the field-corn system, the ears will not be the full, large, hard ears that occur in field corn, and a larger proportion of the nutrition of the crop will be in the stalks than in the ears, than would occur in the field corn system; yet ears would be there approximating the matured state of field corn. The nutrition thus grown on two acres—one in clover and one in corn—would be, as said, greater than that from Timothy; but each in its way would perform in the rotation valuable functions that are indispensable to good farming.

Touching the intimation that an acre each of clover and corn would produce more butter than two acres of Timothy, I take it that no proof need be adduced. All highly tilled farms very rarely fail to give two crops of clover, and a greater yield per acre than of Timothy; while corn is well understood to be our most productive crop. The particular significance of these two crops when considered together is their remarkable efficiency when fed together. This is true not only when they are fed to steers, as I have frequently shown, but it is true for the dairy cow. Corn either in the ear or the fodder, is a good butter maker, and palatable, provided that it is saved in fine condition.

If we measure the problem by the popular fancy for the standard of Wolff, we find that

100 pounds of clover give of protein.			12	26 lbs.
100 "	stover	" " "	15	47 "
100 "	Timothy.....	12.32		"
		12.32		27.73

The analysis of stover is from the Missouri College Farm. So far as we may attach any importance to the great ado made over protein in foods, it will be seen that the combinations are most fortunate and that the two most important cattle foods of the country—grasses excluded—seem made for each other. With these two foods alone, coupled with good pasture, it would be possible to economically maintain good, productive dairies. In my list of old experiments in New Hampshire, it will be found that a substitution of Timothy—where the very nicest grade was grown—for clover and stover, did not result in a gain of milk and butter yield. When stover is cut and crushed (I have used a Lynn crusher) it will practically be all eaten. A shredder was being put on the market in New Hampshire some years ago, that shredded the fodder up somewhat like excelsior, and left it in a most admirable condition for consumption,—better than I have ever seen it. What became of the enterprise I do not know. There is a machine now made in Illinois that husks the corn and crushes and elevates the fodder into a shed or loft.

The time has come when the enormous and wretched waste of corn fodder now going on will largely cease. The country is now getting ready for its use. No food will be found so available and cheap, to supply the needed protein and to bring it into economical use, as clover.

Bulletins 7 and 8 issued by me, will show that I do not find ensilage the best means of utilizing corn fodder, although I do not pretend to prophesy as to what improvements in the silo may yet accomplish. At points in the East where land is high and chemical fertilizers economically available, and where the dairy is made a specialty, especially where the soil is not favorable to grass, possibly Timothy would not become as necessary as here. In that case, we should be met with the fact that clover will not thrive in short rotations, and that some crop would have to intervene between the corn and clover. Some more profitable market crop might be used to extend the rotation. Market demands, soil and location would have to determine the problem. But even then it would not be a dairy crop.

Sheep Husbandry.

CARE OF YOUNG LAMBS.

EVERY year there are a number of lambs in our flock that must either be raised by hand or allowed to perish for lack of nourishment. This arises from a variety of causes; sometimes a ewe will disown her lamb from its birth, or, if she has twins, she will devote herself to one of them and refuse to have anything to do with the other; while another ewe, perhaps, will appear to be very fond of her offspring, but, unfortunately, will not be able to give it a drop of milk; so that rather than see the lamb perish we feed it with milk from a bottle, allowing it to stay with its mother for awhile to see if she will not eventually be able to raise it. We never take one away from its mother when it can possibly be helped, for its natural food is much more wholesome than any substitute.

When a ewe can raise her lamb but refuses to do so, a great variety of influences may be brought to bear upon her. Sometimes if she is confined to a stall away from the rest of the flock, she will make friends with her lamb for the sake of its company. One spring, I remember, we tied a ewe with a rope in order to prevent her from running away from her lamb entirely. For weeks afterward she went about the grass lot with several yards of rope trailing after her, and at intervals somebody had to go out and take hold of the rope to make her stand still. The lamb soon came to understand this, and when he saw us coming would run to his mother, though he well knew that at any other time she would butt him over and over on the grass. The unnatural mother finally became reconciled, and the rope was removed.

Often where there are twins, the stronger will push the weaker one aside until it almost dies of starvation; then if the feeble lamb be fed for awhile it will gain strength and be able to stand up for its rights. One can always distinguish a lamb that is insufficiently nourished by its drawn-up, miserable appearance, and its plaintive cry; and frequently its life can be saved by feeding it for a few days until its mother's milk is more abundant. In such cases, it should remain with its mother, and the bottle should be carried out to it several times a day. Last week I noticed a beautiful little lamb in this condition, and, after it had been fed for several days, it grew so gentle that, as I passed by it while it was lying down in the yard, I held out the bottle which was intended for another little fellow, when, without rising to its feet, it seized the rubber and began drawing away. If a young lamb objects to the taste of the milk, it should be slightly sweetened for a few times, as that seems to make it more palatable.

Some years ago, when we began to take charge of the motherless lambs, we killed one or two from over-feeding; their appetites are insatiable and are no guide whatever. Now we have found that for a very young lamb, a scant half-pint at intervals of about two and one-half hours is sufficient.

They should be fed the first thing in the morning and the last thing at night. As they grow older, the intervals between meals should be lengthened, and the quantity of milk increased, until, when they are one month old, they can take one pint four times a day; and when two months old, they can drink one and one-half pint three times a day. Lambs can live on a much smaller quantity than this, but if they are stinted, their appetite prompts them to graze too freely before their digestive organs are developed, so they fill their stomachs full of grass, and, being unable to assimilate it, their bodies assume that distended, unnatural appearance so common to pet lambs, while their growth and true development are checked. Until lambs are a month or six weeks old, the milk should be warmed, and, if any indications of scours appear, it should be boiled for a few times. Boiled milk should not be given them constantly, however, for it has a tendency to produce the opposite effect, which habit will surely prove fatal if allowed to prevail for any length of time. A small quantity of white sugar or molasses put in the milk will have a laxative effect, and, in extreme cases, a tea-spoonful of castor-oil administered in milk once or twice daily will generally prove a corrective.

So well have we learned to manage the lambs, that now the pets are often considered the handsomest and the healthiest lambs in the flock; and last fall a buyer came and selected one to keep, saying he was the finest sheep he ever saw.

By this time so many of the lambs have been raised as pets that the whole flock has become gentle, for, seeing the pets come and eat from our hands, emboldens them to come too. This makes them more easily managed, for when it is necessary to change the flock from one field to another, we call the pets, and the rest of the flock follow them. Last spring we concluded it was too much trouble to fix the bottle every time the lambs had to be fed, so we taught them to drink milk from a shallow pan, as the milk-man teaches his calves to do, but, unfortunately we never could get them to drink the milk unless a certain person's hand was in it, and that was very inconvenient, for when the favorite individual was absent, the lambs refused a substitute, and would bleat most piteously for half a day at a time. This year we went back to the old method, and now any one can feed them, for the bottle and rubber are always the same.

When the weather was very cold and the lambs were young, they were kept in a big box in a corner of the kitchen; now they are out in the garden on a pile of straw in the sunshine. A FARMER'S DAUGHTER.

RURAL SEPCIAL REPORTS.

Canada.

VICTORIA SQUARE, Ont. August 21.—The potato crop in this neighborhood is poor owing to continued wet weather after planting. A number planted the second time. No appearance of rot so far. The crop will probably be about half an average one. W. S.

Connecticut.

WESTON, Fairfield County, August 19.—The potato crop is rotting badly. Some of my neighbors say they will not have enough for their own consumption. I should say there will not be more than one-half an average crop. Of course, there is nothing accurate about this, as they may continue rotting. Enough has not been dug to demonstrate to what extent they are rotting. The general opinion is they are doing badly. C. E.

Delaware.

KENTON, Kent County, August 19.—I have talked with my neighbors on the probable yield of potatoes: they say they have an average crop and that there is no rotting except on low land. I dug some of mine 10 days ago and found them in good condition. Farmers do not grow potatoes very extensively here, they go in more for grains, peaches, etc.

R. P. M.

Illinois.

CORINTH, Williamson County, August 26.—The potato crop in our neighborhood is very good. I do not hear any complaints of rot as yet. Irish potatoes are not grown much here except for home use; most of the people use sweet potatoes altogether. Corn is an immense crop this year. Apples are a good crop, markets glutted; peaches half a crop. Small fruits plentiful. Wheat is the best crop in years. The chinch bugs gave Southern Illinois a rest this year. J. K. M.

Iowa.

SENEY, Plymouth County, August 19.—Potatoes are in splendid condition. They never rot here. No bugs this year. We shall have a 25-per-cent. better crop than usual. Not many potatoes are shipped from here. Prices range from nothing to $1.25 per bushel. J. P. V.

WATERLOO, Black Hawk County, August 26.—Potatoes are a good crop in good condition, though cut a little short on account of the dry weather. Good crops in general. S. S.

Michigan.

HARRISVILLE, Alcona County, August 26.—The crops here are just immense. Not a failure in any single farm crop. Fall wheat is a little shrunken, but the machine shows a yield from 22 bushels the lowest to over 37 bushels per acre. Spring wheat is not harvested but is plump and heavy. Oats are the best I ever saw, especially early sown, yielding, so far as tested, 12 to 15 and over bushels per 100 sheaves, and there are plenty of fields that turn 500 machine-bound sheaves per acre. Potatoes never looked better. No signs of rot. We have had just enough rain and at the right time. I am testing Rural No. 2 potatoes with four other varieties, viz. Early Rose, White Star, Beauty of Hebron and White Elephant. Present appearances are against the Rural No. 2, but we can't decide till they are dug. I took 10 eyes of each and planted in a trench of 60 feet, in fine garden soil. The trench was dug eight inches deep, a compost of muck and hen manure was placed in the bottom, then two inches of fine soil were raked over it; each eye was placed carefully and then two inches of soil were raked over, then a good dusting of wood ashes and more soil finished the job. All grew but one eye of Beauty of Hebron. I will send statement of yield when dug. I saw in a RURAL some time since that you would copy into the RURAL any good photograph relating to rural affairs. We have a picture of my wife feeding a flock of prize Legborns; also one of our two pet deer, doe and fawn; also a thrashing machine at my barn with teams, 14 men, etc. Three or four years ago 12 of us farmers formed a company and bought a $600 thrashing machine direct from the manufacturer, thereby saving $90 agency fees. One cent per bushel for fine and two cents for coarse grain have covered expenses for thrashing, only when some breakage occurred. [R. N.-Y.—Send the photographs by all means.] W. A.

BIG RAPIDS, Mecosta County, August 26.—The dry weather will reduce the early potato crop in size and quantity to one-half or two-thirds of a full crop; late potatoes are suffering from a like cause and present prospects are about the same; the vines are dying. We have seen no rot. We had a heavy crop of hay and good oats; wheat is a small yield, averaging 12 to 14 bushels per acre. Corn is suffering from the dry weather and an early frost. H. A. B.

HOWELL, Livingston County, August 28.—I hear no complaint in this section of country about potatoes rotting. It has been so dry all summer, and is still. They are about one-half of an average crop. C. P. J.

MILK FOR POULTRY.

B. L. T., Bergen County, N. J.—Is milk a good food for poultry? I see it frequently recommended by farm writers; but an old poultryman, who has raised thousands of chickens, says it is bad for young chicks. What are the facts?

FROM ORSON WINANS.

As to the value of milk and butter-milk for poultry, I have found them very beneficial when fed in moderate quantities; but I would not advise too liberal use of the latter, as it would be likely to produce diarrhea in chicks, and even adult birds if allowed to gorge themselves with it. Both contain a considerable percentage of bone-forming elements, and supply a good substitute for a meat ration, where the birds are not supplied with the latter.

Oak Hill, N. Y.

FROM SAMUEL WILSON.

I have always considered sour milk injurious to all kinds of poultry excepting ducks, unless it was made into curds. When made into curds it is the best feed for young chickens and turkeys. If fed otherwise, it will scour them and have a bad effect. It seems to be different with ducks. They will thrive and do well much better if fed sour milk or buttermilk than they will without.

Mechanicsville, Pa.

BAGNARD BLACKBERRY. From Nature. See page 606. Fig. 232.

FROM C. S. COOPER.

I have found milk unprofitable for young chicks. I discarded its use several years ago. It invariably was too loosening to the bowels in its free use. I have lost whole clutches thereby. For old fowls I have found a limited quantity not injurious. I never fed the mature birds to excess, so that I am not prepared to state as a fact that it is injurious.

Schraalenburgh, N. J.

FROM PHILANDER WILLIAMS.

My experience in feeding sweet or sour milk to chickens is that at first it does not seem to agree with them; but after they have become accustomed to it, it is good. Beef scraps act in the same way: at first the food makes them scour, but after they have had it awhile they do well.

Taunton, Mass.

FROM JAMES RANKIN.

Milk given in a liquid form is not good for either chicks or ducklings as they are so fond of it that they will stand and gorge themselves with it until it runs out of their bills. But when it is used as a mixture with their ration it is the best food extant. I cannot give enough of it.

South Easton, Mass.

FROM P. H. JACOBS.

For fowls I find milk, butter-milk and curds excellent if renewed daily, but for chicks fresh milk only should be used. Milk soon undergoes decomposition, and if kept where chicks have free access to it, or if the vessel containing it is not cleaned daily it will cause bowel disease in chicks. Like everything else, it should be given in a proper condition, and not remain for days in vessels unused by the chicks. The best results are obtained when the milk or butter-milk is used as a mixture in food that is to be cooked or scalded. The residuum of all food should be removed when the meal is finished.

Hammonton, N. J.

FROM O. K. LANE.

Too much is many times expected of milk for poultry as with roots for stock. The domestic fowl is not like the woodcock—it cannot subsist upon suction alone. It must have grain, at least once a day—at night. If there is any one thing on the farm that demands a varied diet more than another, it's the poultry. Consider the easy digestibility of milk in the mammalia. The same in young chicks. A chick when two weeks old, and a colt or calf when four weeks old, are about of the same age, and neither has use for heavy grain. Curd from clabbered milk with an occasional boiled egg is good; for young chicks as well as fowls have a distaste for sloppy feed. Never give food and drink mixed. I'm talking about fresh clabber or fresh butter-milk, not something taken from the swill barrel that's a month old, so acid that it eats the tin from the dipper. To expect chicks and adult fowls to thrive on this alone from June until January, would be folly. Both milk and roots are a light diet; but both are worth more than is shown by their analyses in feeding values, as both aid digestion, and tone the system. Both are appetizers that counteract fever, etc. Curd slightly seasoned is best for young chicks.

Indianola, Ill.

BUTTER FROM CENTRIFUGAL CREAM.

L. B. S., East Springfield, N. Y.—Can the best quality of butter—as good as the well-known Darlington or Philadelphia butter—be made of cream raised with a centrifugal separator?

ANSWERED BY T. D. CURTIS.

I know of no reason why "the best quality of butter—as good as the well-known Darlington or Philadelphia butter"—cannot "be made of cream raised with a centrifugal separator." There is nothing about the mechanical operation to in any way injure the cream or depreciate the fat in it. The quality of the butter does not depend in the least on the mode of separating cream from the milk, but on its quality and condition when churned. The quality depends on three things: 1, the breed or characteristics of the individual cow; 2, the feed—including air and water, which are really elements of nourishment and production; and, 3, on the manner of handling the milk and preparing the cream for the churn. There is nothing that I know of which will change the idiosyncrasies of the individual cow. There is not only the peculiarity of the breed, common in a general sense to all cows belonging to it, but the peculiarity of the individual, which is a part of its individuality, and cannot be altered by any sort of feed or treatment. The food is that from which the cow elaborates the milk, and it determines its quality and flavor so far as not varied by the individuality of the cow. As surely as we do not gather figs from thistles or grapes from thorns, we do not get the best of milk from the poorest of food, no matter what kind of cow-machine we may use in its manufacture. The cow must be right, and the food of the proper kinds, in due proportions, in order to get the most and best milk for butter, or other purposes. The cow and the food being right, the milking done in a cleanly and expeditious manner, and the milk subsequently kept free from taints, odors, the germs of microscopic life, and all uncleanness, the centrifugal separator—if also clean and sweet—can do it no harm. The cream may be afterward injured by improper handling, but this will be no fault of the machine, which will deliver it all right, although any injury done to the cream or butter from improper handling may be attributed to the machine. Such errors are much too common, and should be carefully guarded against. But if the cream is properly ripened and prepared for the churn, there is no good reason why the perfection attained up to the delivery of the cream by the separator may not be continued into the butter, and a perfect article, humanly speaking, may not be the result. But it may be overchurned, it may not be properly freed from butter-milk or caseous matter, it may be imperfectly salted, poor salt may be used, it may be over-worked, it may not be properly packed or prepared for market, and it may be injured by exposure after it is made. All these points depend on the dairyman, and not on any mode of cream separation. And then, when made in the perfection of the art, it may not suit the taste of the customer! Tastes vary—they are educated and whimsical. Butters, like cows and men, have their individuality. No two cows, no two herds, no combination of herds, will turn out butter exactly alike. An article superior to the Darlington in all its details of production and manufacure, might not please the palate of one of the Darlington customers. Some actual imperfection in their butter, to which their patrons have become accustomed, may be the one thing essential to please their palates! A well-authenticated case showed that the presence of a large amount of butter-milk in the butter was indispensable to please the customers. Yet this is not a characteristic of perfect or of even good butter. It is a sad defect that would soon bring ruin to the butter, and its effects, even with those who prefer it, can be avoided only by delivering the butter daily in small quantities that will be at once entirely consumed. So it is, many men with many tastes as well as many minds, and what is perfection to the palate of one may not be so to that of another. The judge as well as the quality of the butter has to be taken into consideration, and people are not always reasonable about this. A case in point will illustrate, although it pertained to cheese, instead of butter. I was called upon at a State fair to pass upon some cheese, in accordance with a standard and scale furnished by the society. A noted manufacturer got no premium and complained. I showed him the defect in his cheese. He said I ought to have taken into consideration the fact that he made it soft and weak for home consumption! So butter may be loaded with butter-milk—just what the maker's patrons want in it—but an expert, judging of butter for the general market, would have to condemn it for this very reason. But, to conclude, there is nothing about the centrifugal separator or its work, when properly done, that need to injure cream, or the butter made from it. The quality depends on other things outside and independent of the mode of separating the cream from the milk.

BLACK-ROT IN TOMATOES: FIRE-BLIGHT IN PEAS.

F. K. P., Delevan, Wis.—1. What is the best remedy for black spots or rot on the blossom ends of tomatoes? 2. What can be done to prevent fire-blight in the pear?

This I believe to be due to sun-stroke causing a sap ferment or poisoning of the sap, owing to weakness or imperfection in its constituent elements. The prime cause, I think, must be a lack of perfect sap elements in the soil. This supposed first cause may be aggravated by planting blighty varieties in extra blighty soil or location and by wrong management. What we want is some simple preventive or corrective of this blighting predisposition.

On August 28th last, after a season of severe suffering from blight (undoubtedly communicated from large old, constantly blighting Hoopes Apple trees in an adjoining village lot), in a fit of desperation I painted the trunks of every young apple or crab on the place with thin white-lead and linseed-oil paint—say 50 in all: eight large trees 35 years planted were not painted. This season several of the eight old trees were somewhat blighted about as they had been last year, and the neighbor's old Hoopes trees were blighted very badly; but the painted young trees have nearly all escaped. I don't believe there is over five per cent. of last year's blight among them and what little there has been was mostly directly under the large old blighting trees. The first fire-blight I saw among the young trees was on a young fall-transplanted, unpainted tree. The blighted limbs were cut off and the trunk was painted on June 15, with some thick brown paint which was also applied to young thrifty Russian pears with good results. Linseed-oil alone may be as good; but up to date—August 5—I detect no harm from the paint on the trunks, though, of course, it is yet too soon to come to a final verdict. Harm may develop later; but I feel more and more sure that fire-blight is preventible.

ANSWERED BY B. T. GALLOWAY.

1. Recent investigations of the black-spot or black-rot of the tomato lead us to believe that this disease is due to the presence of a minute microscopic fungus, which, as a rule, attacks the flower end of the fruit, and by its growth within the tissues of the latter produces the effects with which all are familiar. The black, velvet-like substance which covers the diseased parts is made up of thousands of spores or reproductive bodies, which are borne on short, dark-brown stalks. The spores germinate readily, and if a few of them are placed in the skin of a healthy tomato the disease soon manifests itself at that point. In regard to treatment, very little can be said, as, so far as I am aware, no experiments have been made having a bearing on this question. There is no doubt, however, that the fungus lives over-winter in the rotted fruit, and for this reason the latter, together with the old vines, should be burned after the first heavy frost.

2. It has been pretty thoroughly settled that the so-called fire blight of the pear is due to a living organism, a germ or bacterium, which, developing in the sap, produces the effects with which we are familiar. Ten years ago Prof. T. J. Burrill noticed the connection of bacteria with blight, and since that time his observations and experiments, which have been verified by other scientific investigators, clearly demonstrate that a certain bacterium is the true cause of the trouble. The results of F. K. P.'s experiments in the treatment of this disease are interesting, as they would lead us to believe that it is possible to protect the trees against the attacks of the germs. It is hardly probable that the treatment described would be practicable on a large scale, as in order to render the tree germ-proof by this method, it must be literally enveloped in a coating of oil or paint. The question here arises as to whether there are not some parts of the tree more vulnerable than the rest, through which the germs gain entrance, and, it this is the case, whether we can not by rendering these parts germ-proof save the whole tree? As a matter of fact, it has been shown by careful observation that the two most vulnerable points for the attack of the blight germs are the flowers and the tips of the young branches. If these could in some cheap, practical and efficient manner, be protected, it might be possible to hold the disease in check. As an experiment having a bearing on this question, I would suggest that next spring F. K. P. should select a half-dozen pear trees which are subject to blight and treat four of them as described below, leaving two for checks:

About the time the flowers are opening, spray with a solution made by dissolving three ounces of carbonate of copper in one quart of ammonia diluted with water to 22 gallons. With a good pump and nozzle a large tree can be thoroughly sprayed in a very few minutes. Care must be taken, however, to reach all parts of the tree. Repeat the sprayings—say every 10 days—until five applications have been made, and if the remedy has any value for the case in hand this ought to prove it.

CREAM NOT RISING.

S. S. K., Ellensburgh, Washington Ter. Why does my cream not rise? The temperature of my spring is 50 degrees. Just below it is a place in which the milk cans are placed just as soon as the milk in them has been strained. The cover is removed enough to let in the air. If the milk is left there three days and then skimmed, and it is then left standing another night quite a mess of cream rises. I have read of cream rising in 12 hours; what is the matter with mine? My cans are 18 inches high and eight in diameter. Is the temperature too high or too low?

ANSWERED BY HENRY STEWART.

The difficulty is unquestionably in the temperature, which has much to do with the separation of the cream from milk. When it is considered that at 32 degrees water is solid and at 33 degrees it is liquid and this great difference in condition is due to only one degree of temperature, every person who has to do with milk and cream should realize the effect of temperature and the absolute necessity of using a thermometer. Cold and heat are relative, and appear very different to the sense of feeling from what they really are under varying circumstances. When the heat of the air is 90 degrees, water at 60 feels very cold, and quite as much so as water at 40 degrees with the air at 60 degrees, so that your "really cold water" may be really no colder than 60 degrees which is the best temperature for setting milk in shallow pans; while for the deep pails you are using 45 degrees is the right temperature. Even very cold springs are rarely as cold as 50 degrees in the summer, and while deep pails may be used in water of this temperature the cream will not be fully separated before 24 hours, while with water at 45 degrees 12 hours will be sufficient and even six hours at 35 or 40 degrees.

A thermometer should be used to test the temperature (one will cost 25 cents only) and if, as appears probable, the temperature of the spring is not less than 55 or 60 degrees, the milk should be set in the common stone-ware jars used for the purpose, which are about eight inches deep and seven inches wide, as these take up less room than the tin pans used for shallow setting; or tin pails not more than seven or eight inches deep and holding about six quarts may be used. There will then be no trouble in getting the cream.

LIMING LAND.

A. J., Lincoln Park, N. J.—I want to seed down a piece of ground with grass along with rye. It needs a coat of lime, as there is a good deal of sorrel in it. After plowing the ground and applying a good coat of manure and cultivating, would it do to put on a good coat of lime, and harrow it in? Would the lime interfere with the action of the manure?

ANS.—Lime is not necessarily antagonistic to sorrel: because sorrel is acid and lime alkaline. It by no means follows that lime will kill out the sorrel. Sorrel will grow luxuriantly about lime-kilns, and especially on land where piles of timber have been burned in clearing, and yet the ashes contain 30 to 60 per cent. of lime. But sorrel, as well as other weeds, may be run out by enriching the land, so that the crops will smother the weeds. It is quite common in localities where lime is used regularly to manure the land, plow it, and then apply the lime, harrowing it in. The action of the lime is not at all injurious, but rather beneficial, as it tends to decompose the manure, and develop nitrogen compounds in the soil, and so largely favors the growth of the grain crop and the grass and clover which succeed it. This practice is quite common in parts of New Jersey and Pennsylvania, where the most successful and thrifty farmers are to be found.

Miscellaneous.

M. B P., Henderson, N. C.—I send the RURAL the leaves and a twig of a bush that grows here in the woods and fields and by the road-sides; what is its name?

ANS.—It is the Wild Papaw (Asimina triloba.) The fruit is very good to eat. But it contains too many large seeds in proportion to its amount of pulp to render it of much value for market purposes. In home use, however, it is desirable and a pleasant change.

G. R. W., Lyndon, Ky.—What is the origin and parentage of the Amber Queen Grape and also of Norwood and Arnold's Hybrids, 1, 2, 5, 8 and 16?

ANS.—We do not remember the originator. It is said to be a cross between Marion and Black Hamburg. Norwood is a Labrusca. Arnold's No. 1 Clinton and Black Hamburg; No. 2 Clinton and Black St. Peters; No. 5 Clinton and Golden Chasselas; No. 8 Clinton and Black St. Peters; No. 16 Clinton and Black St. Peters.

W. R. U., Bake Oven, Oregon.—What are the principles on which the various sheep-shearing machines are constructed?

ANS.—We do not know that these machines are made in this country. We have heard of their use in Australia and presume they are manufactured in England. The principle employed is that of a horse clipper run by a machine similar to that used by dentists, by foot or steam power. It is said that the machines are not fully successful yet and that they cannot be used on Merino Sheep.

A. A. M., Walworth, N. Y.—Would it be advisable to mix plaster in equal parts with hen manure and ashes? The ashes are unleached and the hen droppings have been accumulating for several years. What amount of the mixture should be drilled in with wheat this fall?

ANS.—Our way would be to sow the hen manure and ashes separately and harrow, not drill in. The amount is a question for our inquirer to decide. We know nothing of the present condition or fertility of the land. You need scarcely be afraid of using too much of the ashes. All the way from two to five barrels of the hen manure may be used.

DISCUSSION.

COUNTRY SCHOOLS.

FRANK HADLEY, UNION COUNTY, N. J.—An article on the Country School, page 550, while containing some excellent suggestions, is decidedly Utopian in other respects. The first three questions suggested may apply truthfully to many, if not to most, of the primary grades of our city and village schools, but I am of the opinion that they are uncalled for as applied to what are commonly known as country schools, *i. e.* to those outside the cities and villages. The average duration of the public schools of the United States, according to the report of the Commissioner of Education for 1887, is 27 weeks per year. As the city and village schools generally approximate 40 weeks per year, it will readily be seen that some of the country schools fall far below this average, while few of them exceed it to any extent. As children are usually confined in the country schools only about five hours daily, for five days per week, I think there is little danger of their "making haste" too rapidly, or of "drawing too heavily upon the nervous force of childhood." In all my experience in country schools as pupil, teacher and looker-on, I have observed more injuries to children during the hours of recreation than ever were suffered mentally by too close confinement or application. The suggestions contained in the last two questions are valuable. Anything that will lead the child to closer habits of observation, to a more careful study of the myriad forms of animal, vegetable and insect life with which he is so constantly surrounded, will lead to a higher appreciation of the beauties of Nature, and a greater love for rural life. The country-dweller is constantly surrounded by so many interesting objects that it is too bad that his interest should not be awakened to their beauties when a child at school. The pupil in the country school should learn the names, uses and distinguishing characteristics of the common plants he daily sees. Then he should be taught to observe how others resemble these and thus to group similar ones together. Do not frighten the wits out of the child by telling him that he must study botany; when he studies plants he is studying botany pure and simple, but he doesn't know it. The main object is to get him interested, to arouse the spirit of investigation. He should learn of the birds and animals he daily sees, the insects by which he is surrounded. He should learn their habits and mode of life, should know which are the friends and which the foes of the farmers; should be taught to protect those which are beneficial. These and many other kindred subjects should have a place in our country schools. Then the practical application of the common branches taught should be enforced. I have seen scholars well advanced in ordinary branches, who could not acertain the number of cords in a pile of wood of given dimensions; who could not find the cost of plastering a room of certain size and shape, or tell how much carpet was necessary to cover the floor. Many who can conjugate, decline, parse, and give all the rules and definitions in an ordinary grammar, could not write an ordinary letter correctly. These and many other practical things should be taught. When the people demand them they will be, but there will be some tremendous shaking among the dry bones of educators first.

THE RURAL'S NEW CUTS—WESTERN PRACTICES.

J. M. D., MINNESOTA CITY, MINN.—The RURAL for August 24, with its new super-calendered paper and consequently improved photo-engravings, came to-day and I have been comparing it with old, back numbers. How much we owe to photography and the new methods of cheaply reproducing photographic pictures! To comprehend and appreciate our present blessings fully, one has to compare the pictures of the Jerseys and the blackberries in this week's issue with the pictures of stock and fruit to be found in old numbers of MOORE'S RURAL. The reader who would pass by that "group of grade Jerseys" as an ordinary picture of a lot of cows, is incapable of getting what he should from a good paper. The words, "From a photograph" under the picture, are not needed to distinguish it from an ordinary engraving.

The RURAL'S idea of having its readers send photographs of useful implements, etc., is a most excellent one. Hundreds will be interested in the promised picture of Mr. Terry's tools and machinery. This morning, as one of our men started for market with 95 bushels of barley, I longed for a camera so that I might show the RURAL readers how it was done. In this section where the roads are not so good or so wide as in Ohio, it would be impracticable to use Mr. Terry's three-horse wagon; so, as the next best plan, we use four horses and a rather heavy wagon with low, wide-tired wheels. This plan saves the labor of one man and one wagon. We are three miles from the station, and make four trips a day. Forty-five sacks of grain make a rather high load; but with fairly good roads there is no trouble. We bind the load with ropes extending from the braces under the footboard, back over the load and down to the rear axle. Four horses accustomed to pulling together make a powerful team, and are easily handled. We always use four on the binder even when three would pull it easily enough; for the reason that the lead team can pull the machine around at the corners of the field so much more easily than could those on the tongue. For the lead team we use a light set of whiffletrees with large harness snaps for hooks—these never come unhooked without help. The leaders' lines should extend directly back to the driver without passing through any rings on the bridles or harness of the tongue team; in this way they will be free, so that the driver may use them to slap the leaders if they are inclined to be lazy. If a gentle slap with the line is not enough to keep a leader up to his work, fill the tool-box full of small stones and use one occasionally, always calling the horse sharply by his name just before the stone hits him. Of course, no RURAL reader will misunderstand me and think that I would use cobble stones; a stone larger than a hickory-nut would be too large to throw at a horse. A horse that would need touching up oftener than once or twice a day should not be used on the lead. Don't attempt to use a whip long enough to reach the leaders, especially on a binder; it would take too much time to disentangle it from whiffletree-hooks, reel, packer shaft, etc.

PASTURING MEADOWS.

H. L. W., NEWBERN, VIRGINIA.—In regard to pasturing meadows after mowing, I am inclined to the opinion that, as a rule, it is a bad practice. If it were done in moderation—not closely—say from November 15th to December 15th, it would not be so very objectionable; but it is customary here to stack the hay on the meadows, and feed it out to cattle on the land all through the winter till late in spring. As a consequence, the grass is cropped till the earth is bare, and the soil, especially if clay, is tramped as solid as a brickyard. It is easy to see that all the droppings and waste from the cattle will not compensate for the injury done. Meadows composed of Timothy or clover and Timothy, suffer the most injury. Timothy makes comparatively little aftermath—scarcely any when cut late, and needs all it makes for its protection. Sprouting from a bulb very near the surface, it is easily destroyed, if that is bitten off or crushed from tramping. Orchard Grass makes an abundant aftermath, which can be grazed closely without sustaining any serious damage. Blue Grass makes a sod so close and firm that poaching does not injure it to any extent. Sandy soils are often benefited by feeding on them, the firming given in this way being just what they need, nor are they injured in wet weather as other soils are. On the whole, I should not advise the pasturing of Timothy or clover meadows at all, unless in the case of the latter, there might be chances of the after-growth smothering out the plants, as I have known occasionally to happen; but Orchard, Blue and grasses of a similar character might be cropped till the coming of very cold or wet weather.

BLIGHTED HOPES—BLIGHTED VINES.

"A DESPONDENT CONTESTANT," BOONVILLE, N. Y.—Alas! How often do our anticipations exceed our realizations? Last spring how joyfully we planted our prize potato patch, taking extra pains with it, firmly believing at the time that in the fall that wonderful patch would walk off with one of the first prizes, besides supplying all the city markets too, thus making us millionaires before 1890 could be ushered in. Alas for human calculations! Little did we think we'd

ever have to toil after we had once pocketed the proceeds of that potato patch! Oh! how those potatoes did grow at first! How with honest pride we'd exhibit those massive vines to all our friends! How threatingly we did look when the first bug appeared, and how we captured his many relatives and friends as they made their appearance; giving them a liberal supply of kerosene and adding a lighted match, we would watch them breathe their last. Finally the vines became so large that we used Paris-green by means of a force-pump. Then it began to rain, rain, rain, until those potatoes were nearly drowned, and to accentuate the climax, the rust settled on them too. I guess the potatoes died an early death, for decomposition has set in in the remains very badly. When I read Fred Grundy's piece a short time ago, I pitied him and his wife; but now I feel that we can extend a sympathizing hand to them, and say we know just how it is, for we've been there, too.

KILLING WOODCHUCKS, ETC.

D. E. G., NORTH LEVERETT, MASS.—In a late RURAL I saw the caption "How to get rid of woodchucks." Here is the way in which some get rid of them here. Put in the woodchuck's hole a quarter-pound charge of dynamite, with cap and long fuse attached, and stop up all the openings, just leaving the end of the fuse outside of the one in which the dynamite charge was placed. Then touch off the fuse and the animal will never trouble you again. If dynamite is not at hand, fill a small bottle with common blasting powder, insert the fuse through the neck of the bottle, and fasten it there with a convenient stopper. Use and fire in the same way as the dynamite charge. Another way is to burn a quantity of brimstone, mixed with dry sawdust, inside of the woodchuck's hole, stopping up all the openings, and thus choking the pest to death.

Next year try black pepper for striped squash bugs. Winter apples are all falling off here.

"THE COST OF LIVING."

E. H. C., MATTSVILLE, IND.—Here are some items from our book account for the years 1887 and 1888. The items represent the money paid out during each year for the various articles.

	1887.	1888.
Sugar	$12.25	$13.75
Coffee	6.47	4.48
Baking Powder	2.95	2.10
Tea	1.00	.75
Flour	16.00	17.10
Total	$38.67	$38.18

The farm furnishes the finest White Clover honey in abundance, also maple and sorghum sirups, as well as hops, milk, etc., all of which are in unlimited quantity, so far as home consumption is concerned, and, of course, affects our grocery bill. We have a family of four, including two children, and there is one hired man on an average about all the year, making five in all.

MORE SILO CROPS.

J. A. B., NEWBERG, OHIO.—I never have put in a silo anything but corn, except rye. This was a failure. I tried clover this year; but did not get good results, because I broke my cutter when only a few loads had been cut. Before I could get repairs done the clover was too ripe and what little I had cut, not being weighted, was moldy. That clover or millet will make good silage I have not the least doubt, because others have tried them in this section and have had good results.

"W.," TYRONE, PA.—Have those who tried baling fresh-mowed grass stored their bales at once in a silo, or in an out-door stack compressed by screws as seems to be much practiced in England for keeping silage? Obviously this is necessary to keep the air and germs of mold from entering the bales. The advantages of this baling in the field would—if it can be made a practical success—be so very great that a complete trial should be made by those who have the opportunity before the idea be relinquished.

C. H S, STERLING, ILL.—In the RURAL of September 15, 1888, speaking of the gooseberry, mention is made of a foreign variety received from H. Summer in 1884. Is not this the one I (C. H. Sumner) sent to the RURAL from Polo, Illinois, with the statement that it had been imported from Ireland? The description tallies exactly with my plant, which I am still having tested.

R. N.-Y.—Yes it is the same.

J. H. B., BRITISH COLUMBIA.—Will some one conversant with the subject tell us in the columns of the RURAL NEW-YORKER the best season of the year to trim (thin out the tops) of fruit trees—apples, pears, plums cherries—and give such general directions as shall be of benefit to those who know little or nothing about it.

What Others Say

MULTUM IN PARVO.

It may be seen by our advertising columns that the promising novelty, the Idaho Pear, is now, for the first time, offered for sale. The R. N.-Y. was the first journal to describe and illustrate this remarkable fruit—remarkable in form, quality and fewness of seeds. We hope it will be tried in every part of the country .....

SINCE the "Short's Method" of determining fat in milk was published, the Vermont Experiment Station has made many trials with it and in the main the results have agreed fairly well with the ordinary laboratory method. The only change it has found necessary to make in the method of using it, was to heat considerably longer than the instructions call for. It seems necessary, however, to call the attention of those who intend to make use of this method to the liability of getting tubes which are not properly made and hence worse than useless. The Station has bought sets of tubes from three large firms whose names are each considered a guarantee of good work and only one of the firms sent reliable tubes. This was a wholly unexpected danger and one that, unless immediately avoided, must quickly bring the Short's Method into disrepute. There is reason to believe that each of the firms that sent out incorrect tubes has since made a new supply of correct ones, but it is probable that there are already in the hands of farmers and creamery-men a large number of worthless tubes that it is desirable should be found out and thrown away. The Vermont Station will test free of charge any tubes that are sent in by express prepaid and will return the same as soon as tested.....

PUT in a few currant and gooseberry cuttings.....

CULTIVATE the asparagus bed and destroy all the weeds.....

PLANTING DECIDUOUS TREES IN SEPTEMBER.—Joseph Meehan says, in Garden and Forest, that August is undoubtedly one of the best months in the year for transplanting evergreen trees, and, he adds that deciduous trees can be planted to advantage much earlier than they usually are in autumn. There is no need of waiting for the fall of the leaf. If transplanted in September such trees would not only do well, but, in very many cases, they would do better than if removed later. A transplanted tree bears some analogy to a cutting. The propagator, in a green-house, knows, when he puts in a cutting, that the sand in which he inserts it should be warmer than the air, and so he gives bottom heat. When a deciduous tree is transplanted in September, the earth and the air are in much the same relative condition as is desired for the green-house cuttings. The warm ground forces out fibers at once, and when cold weather sets in the tree is well established, having an abundance of roots to help it through the winter. This is not a matter of conjecture, but something that Mr. Meehan has tested many times. If any reader, for experiment's sake, will transplant a small tree in early September, and dig it up again in October, the number of new fibers which have been formed will probably surprise him. If trees are planted before the leaves have fallen, these should be pulled or cut off.....

IT is true says Judge T. C. Jones, in the Ohio Farmer, that we are passing through a long period of depression in prices, but, it must be observed that this depression affects the products of nearly all other industries, and the income of all sorts of investments. And it is believed that this depression is not more severely felt by agriculturists than by people engaged in other branches of business. Indeed, the small farmers, a class which, more than any other, aims to produce what they consume, are obviously less affected by depressions and fluctuations in prices than any other class. .....

LET us suppose an intelligent and industrious man with a capital of $1,000 to $8,000 to be seeking to invest it in some business in a town or city that will, with proper attention, yield a profit sufficient to support his family. Would it be an easy matter for him in these times to find such a business and a location where a comfortable living would be assured? On the contrary, is it not true that failures in those vocations of "business" and trade, even where there has been no bad management, no neglect of proper attention, and no extravagance in expenditure, are quite common, while among the class of farmers that Judge Jones alludes to such failures are exceedingly rare?.....

IN doing legitimate business it must be remembered that only a very small number succeed in accumulating wealth; the great majority of even the industrious and frugal class acquire no more than a comfortable maintenance with a good education for their children, and it may be confidently asserted that the farmers of our country more generally possess this competence with the inestimable blessings of frugality, morality, and godly living, than is found to be the case with people engaged in any other industry or business.

THE PHILADELPHIA WEEKLY PRESS knows of a farm where two teams of horses do the work, driven by men who get the same amount of wages per month. Not long ago one of the drivers was ill for a few days and the "boss" took his place behind the plow. Much to his surprise and enlightenment he found that even with persistent nagging the team he was working could make but two "bouts," while the other team made three at their natural gait and without any urging. Here was 50 per cent. more work done in the same time with greater apparent ease. The wear and tear seemed to be the same in both cases. The horses were all fed alike, and were in equally good condition. The team the boss drove was good, but the other was a good deal better. It didn't take very long to settle in that farmer's mind which team was the more profitable for him. This is a true story, and its counterpart could be proven on many another farm .....

IT is encouraging to note that people are waking up to the fact that our civilization demands fast-walking as well as fast-trotting horses. A good many fair associations that never thought of doing so before are offering premiums this season for fast walking horses. This is a move in the right direction. There is utility in a rapid walk. All horses need not trot, but all must walk. As the Arabs say: "The walk is the gallop of always."

THE R. N.-Y. secured, through Robert Douglas & Son, of Illinois, six or eight Russian Mulberry trees, and it was therefore enabled to offer an early report to its readers that this mulberry is quite inferior as to its fruit. Several firms were then booming the Russian Mulberry so that the R. N.-Y. came in for its usual share of reproach on such occasions. It pays to be right in one's condemnations—in the long run.....

THE MAINE FARMER says that Dr. T. H. Hoskins of Vermont, although somewhat advanced in years, has the pluck that would honor even a young man. He has purchased a $2,400 farm and proposes to pay the purchase money, with interest, from the farm in five years; *and he'll do it.* He has 12 acres of potatoes, two of corn and 20 of beans, all nicely taken care of by two men with two horses. As his home farm gives him a living and much more, he seems to be doing this to show to others what can be done when a man knows how and has the courage to go at it. All honor to so worthy an example.....

To the above Dr. Hoskins replies:

"OUR Maine friend is right when he says that personal gain is not our first object in this experiment, though we shall not be sorry to make a little money out of it. What we chiefly seek to do is to prove by actual demonstration that these cheap farms in Vermont are worth a great deal more than they are selling for. If we succeed in this, we hope it will be an encouragement to many others, and indirectly a benefit to the whole State."..

IT would seem from the Maine Station experiments, and from others as well, that there is little profit in grinding corn for pigs.....

THE NATIONAL STOCKMAN and Farmer says that any one reading the glowing crop reports in the sensational metropolitan press, would suppose that Nature was piling up wealth around the farmer in such a way as almost to choke him. It instances a Canadian exchange, descanting on the fine harvest promise of the Dominion, which says in flaming headlines that "rivers of gold are pouring into the pockets of farmers." This kind of stuff makes people of common-sense tired. Somehow these "rivers of gold" get down to wonderfully small rills before they reach the aforesaid pockets. Farmers are of course glad and thankful to have good crops, but in these days they find no occasion for indulging in extravaganzas of gush over this or anything just now falling in their way.....

MANAGER BROWN of the California State Board of Trade has in use a most excellent method for the preservation of the color and beauty of green fruits, says the Pacific Rural Press. Liverpool salt is dissolved in clear water until the brine is strong enough to float the fruit. Let this stand over-night, and then strain through a cloth until the liquid is perfectly clear. Place the fruit to be preserved in thoroughly clean, wide-mouthed jars; fill to the brim with the brine and then close tightly. While this method for a long time perfectly preserves the bloom and color of the fruit, it, of course, unfits it for eating. Twigs with the fruit and foliage attached, when preserved in this way, are exceedingly attractive for exhibition purposes.....

DIRECT.

——T. B. TERRY'S LECTURE: "Make the motto PUSH to hang over your barn door. What's the use of living if you can't improve a little?"

——"THE farmer is very apt to blame the middlemen, the tariff, and what not for his failures, when he need not go beyond his own door to find the fault. Governor Hoard of Wisconsin interviewed 100 farmers concerning their success or lack of success, in 1886, and not one of the many failures was laid at the door of the farmer himself."

——FARM, STOCK AND HOME: "We believe that the happiest angel in Heaven is the one whose business it is to record man's kindness to the dumb animals."

"How exasperating it is for a farmer to be told by the monopolistic thief who has robbed him: 'You must raise bigger crops and economize.'"

——HARPER'S WEEKLY:

"CITY BOARDER: 'Bridget, is this last night's milk?'

BIDDY O'GALWAY: 'It's the cow's, sir.'

CITY BOARDER: 'Ah, indeed! Well, it is sour. How did that happen?'

BIDDY O'GALWAY: 'An' what ilse would yer be expectin', sir? There's the poor bastes standin' in the bilen sun the whole live long day, an' aten sorrel an' green apples. Sure, I'm wonderin' they don't give bonny-clabber or buttermilk.'"

THE
RURAL NEW-YORKER.
A National Journal for Country and Suburban Homes.

Conducted by
ELBERT S. CARMAN.

Address
THE RURAL NEW-YORKER,
No. 34 PARK ROW, New York.

SATURDAY, SEPTEMBER 14, 1889.

WE would be glad to receive a seed-ball or so of the R. N.-Y. Potato No. 2 from any of our readers with whom the variety fruits.

Now that it has been found that Paris-green sprayed upon the trees will kill the coddling moth, people having but little land or small gardens, will be encouraged to plant apples worked on Paradise stock. Trees so worked are well suited to just such locations. Every part of these little trees may readily be sprayed by a hand pump and spraying nozzle, insuring large, fair fruit.

BUT for the rust to which the Kittatinny is especially liable, the R. N.-Y. would to-day, as in years past, select it as its first choice among blackberries. The only other objection to it is that it often sustains injury during severe winters. In so far as can be judged at present, the Minnewaski is a hardier variety not subject to rust. Acting upon this assumption, it would be our first choice. The Snyder and Taylor are about the hardiest kinds known, but they will not sell in any market that is supplied with larger berries.

TO SHOW the serious damage that the potato crop has sustained, even in sections where loss was deemed practically impossible, the R. N.-Y. prints the following note just received. Whoever before heard of potato blight in Colorado?

"LONGMONT, Weld County, Colorado, August 31. Since my report of August 17, on the potato crop, the prospects have materially changed for the worse. Many fields are blighting and the outlook at present is not good for more than one-half an average crop, so general is the complaint of the evil. This is the leading potato county in the State. C. C C."

"The nutriment in an acre of corn-fodder is equal to or really exceeds the nutrition in the corn it bears."—PROF. SANBORN, page 607.

THE soil of most of New England seems to be admirably adapted to the growth of Timothy. At all the local New England fairs are seen samples of this grass so long as to astonish visitors from abroad. Bunches of Timothy six feet eight inches high, taken from a Bristol County, Massachusetts, meadow will be exhibited at Western fairs this year. This grass was taken from new land from which the wood and bushes were cut in the winter of 1888. If Western folks expect the Yankees to be astonished at their great corn and vegetables, they should at least respect New England hay.

MR. N. HALLOCK, of Creedmoor, N. Y., tells us that he saved the seed from the blossom end and stem end of two varieties of tomatoes and planted them separately—giving six plants to each. He found that the plants raised from the seed of the flower end ripened about three days earlier than those from the stem end. This is an important item. Certain it is that the portion of the tomato furthest from the stem (flower end as it may be called) ripens before the flesh *about* the stem, and it seems not unreasonable that the seed earliest matured should produce the earliest fruit. At any rate the question is worthy of further investigation.

IN the printed reports of the Tomato Exhibition recently held at the warehouse of J. M. Thorburn & Co., the origin of the "Station" Tomato is credited to Cornell University instead of to the Geneva Experiment Station. Mr. E. S. Goff crossed the Alpha (as we remember) upon the Tree Tomato some six years ago. One of the results of this cross is an upright, bush variety which bears fruit nearly as smooth as the Alpha and as early to ripen as most of the kinds popular at the present time. This is the tomato now known as the "Station." Mr. N. Hallock of Creedmoor, N. Y., has a strain of this tomato which seems to be quite well fixed. But at the Rural Grounds, plants grown from seeds kindly sent to us by Prof. Goff, sport indefinitely both as to habit and fruit.

AFTER all, the bankrupt Pennsylvania Agricultural Society has managed to make arrangements for holding a State Fair in connection with the York County Agricultural Society's Fair at York, Pa. Upwards of $3,000 will be added in premiums and $1,000 for races above what was originally intended by the York Society. Nearly the whole of this amount, however, has been contributed by York as an inducement to the State Society to lend its name and influence to the enterprise. Some discontent is expressed at its intention to charge a 50 cent entrance fee instead of the customary popular 25 cent fee. It is to be hoped that exhibitors and visitors will lend a helping hand to the crippled society, and liberally reward the liberality of York.

THE scientists tell us that the spores or germs of the potato rot remain in the tubers for a considerable time. In fact, it is claimed that the disease is frequently brought into a field in the potatoes used for seed. The spores remain in the seed pieces until the conditions favorable for their development are supplied. Then the disease spreads. If this be so, the selection of next season's seed will prove a very important matter. In order to insure ourselves from the introduction of rot in our seed potatoes we must obtain seed from districts where rot has not appeared. The R. N.-Y. proposes to try to investigate this matter with a view to disclosing the sections where rot has been least damaging and also to learn how far this idea of danger of rot in seed potatoes may be safely carried.

TO PREVENT rot and mildew should the grape racemes be bagged before the buds open, while in bloom or after the berries have set? To answer this question about 100 bags were used—one-third for each class. Most of the racemes bagged *before* bloom did not set any berries. Several—the Eaton among them—formed and matured perfect bunches. Most of those bagged while in bloom formed imperfect bunches. Most of those bagged after the berries were the size of early, small peas matured berries which were neither more nor less rotted than those left exposed. It is a delicate matter to bag the racemes while in bud or flower and is, in fact, impracticable. As might have been anticipated, bagged buds produce or fail to produce berries as the pistils and anthers are perfect or imperfect.

ONE of the most difficult problems to be solved by the Census Bureau is the best way to secure statistics of mortgage indebtedness for the coming enumeration. If the face of the recorded mortgage showed the amount of the indebtedness, the work would be comparatively easy; but the face indicates only the original debt, and to learn how much has been paid on each mortgage, the mortgagors or mortgagees must be written to or interviewed, and when this has been done the desired information is sometimes refused. It is of much interest and considerable importance that this form of indebtedness should be ascertained; but to do so appears an almost impracticable task. The matter affects farmers, of course, more than any other class, and they should help the enumerators in the work. Several experts from the Pension Office are now conducting experiments in the matter in different parts of the country; but the difficulties in the way of gathering correct information are so unsurmountable that the results must, at the best, be largely approximate.

THIS has been a good year for Kansas farmers; crops, as a rule, have been good and prices promise to rule high. This success should not make farmers reckless. There is danger that it may do so. After a good season it always pays to be conservative. This is on the principle that saving is just as important as earning. On another page of this issue, Prof. Shelton puts the matter in a very forcible way. The excellent wheat crop that has just been harvested has turned the minds of many Kansas farmers. They want to put in more wheat than ever next year and neglect other crops and farm interests. This idea is wrong. Keep out of it. Diversified farming is surest in the end. And this fact applies with equal truth to farmers in other sections of the country. Whenever prices range high for a certain product, there is, among a certain class of farmers, a rush to raise an extra amount of that product the next year. The consequence always is that the market is glutted, prices are lowered and good prices are only obtained for the products that the farmer has neglected. Is not this true?

THE CROP FOR STABLE MANURE.

ONE of the most interesting questions that the R. N.-Y. has for discussion is the best place in an organized crop rotation for the application of stable manure. We find that good farmers differ in their opinions as to the best crop for utilizing stable manure, particularly those farmers who use more or less chemical fertilizers. Many are very strongly in favor of the corn crop, arguing that the corn plant is the greediest plant known to agriculture and the least likely to be injured by rank or coarse manures. Other farmers haul manure on the rye or wheat during the winter, arguing that the grass that is to follow the grain will find the best use for a manure that is supposed to continue its effects for a number of years. Still others have special plans for the use of stable manure. The R. N.-Y. has collected quite a mass of information from farmers in all parts of the country where pains are taken to save stable manure. The rotations employed on various farms, the crops that are used as specialties, how and when the manure is applied, and in fact, dozens of important matters connected with successful manuring will be brought out. This promises to be one of the most important "symposiums" that the R. N.-Y. has ever published.

PROBABLE REPEAL OF TAXES ON TOBACCO AND FRUIT BRANDY.

THERE is a growing movement for the repeal of the internal revenue taxes on tobacco and fruit brandy, during the next session of Congress. In order to reduce the surplus revenue without materially lowering the tariff, the Republicans, as a party, are likely to favor the abolition of some of the internal revenue taxes, and the repeal of those on tobacco and fruit brandy appears to be less objectionable than of those on whisky and sugar, from which most of the internal revenue is derived. It is proposed to begin the work for repeal with the election of the Speaker of the House of Representatives. The Republicans favoring the measure are not to vote for any candidate who will not agree to give a fair parliamentary recognition, in the committees and on the floor of the House, to those who favor the abolition of these taxes. Should all the candidates yield to the demands, each member will be free to vote for any one of them according to his choice. Democrats from the tobacco-growing districts are equally earnest in favor of the repeal of the objectionable taxes, and there is little doubt that they will heartily unite with the Republican advocates of repeal. For years tobacco growers all over the country have been strongly urging the abolition of the tobacco tax, and fruit-growers in those sections where the making of fruit brandy is an important industry, have been equally persistent with regard to the repeal of the tax on that product. There is now a probability amounting almost to a certainty, that by vigorous efforts during the ensuing year, they will so increase the number and strengthen the influence of their friends as to secure the measure for which they have so long struggled.

INTEREST ON RAILROAD INVESTMENTS.

A GOOD deal is being made by railroad men out of recent statistics with regard to the average rates of interest paid on railroad investments. The statistician of the Interstate Commerce Commission puts the general rate of interest on all railroad capital at 3.06 per cent., the lowest being 2 03 per cent. on common stock, and the highest 4.24 on bonded debt. The figures given by Poor, the great authority on railroad statistics, are an average of 1.77 per cent. on all kinds of stock, the highest being 4.35 on bonds. "How can railroad charges be extortionate or in any way unfair," exclaim railroad men, "while the interest paid to stockholders on their investments is so pitiful?" How much of the aggregate stock on which interest is paid, is "water," on which no interest should be paid? What is paid on the enormous mass of water, however, lessens by just so much the interest payable on cash.

Then again, how many railroads are built or run for the benefit of the mere stockholders? Isn't it a fact that a large proportion of them are "worked" mainly, if not entirely, for the benefit of their speculative directors and managers? Have Jay Gould and others of his kind, piled up their millions from the legitimate interest on their investments or from their tricky manipulations of the vast interests in their charge, in the financial markets, for their own private advantage? How can stockholders expect high interest on their investments in railroads a large part of whose capitalization is very dirty "water," and whose interests are manipulated by speculating managers for their own individual emolument? And why should the public be expected tamely to reimburse them for the shortage due to the unscrupulous greed, trickery and knavery of their own officers?

"Better a little under or over-ripe than spoiled hay." * * * * *"The Lord never planted cat-tails on a dry hill-side, but I have known farmers to try to raise celery in gravelly sand."*—PROF. ROBERTS, page 607.

BREVITIES.

TRY the Minnewaski Blackberry. Try the Erie.

ONE of the most appropriate and valuable trees for cemeteries is the European Weeping Beech.

JUST now the Minnewaski is giving us the largest and best blackberries of those bearing so late.

THE dry, hot weather of the last two weeks has improved the R. N.-Y's corn crop wonderfully.

"THERE, now, good little boy, you have done the work nicely. Run off and have a good play."

THERE is a demand for first-class butter at good prices, although the market is flooded with poor trash.

IS not fodder-corn cut at just the right time and well cured as good for old horses as Timothy hay?

PEAR trees lost their leaves 10 days ago. Now, many of them are making a second growth and bloom.

IF you would increase the size of the Snyder Blackberry, give it close pruning, plenty of room and high culture.

WERE it not for the California and tropical fruits, it is doubtful if the supply in this city would equal the demand.

"LARD Compound" was the inscription on some barrels which were being rolled into one of the large city bakeries. Next!

GOOD peaches are not plentiful, and sell readily at paying prices. Tomatoes are a drug on the market, and the price is low.

THE objections to the several kinds of white blackberries tried at the Rural Grounds are tenderness of cane and unproductiveness.

THE apple crop in the United Kingdom is poor, and the demand for "fruit of good size and quality" from this country will be good.

TRANSPLANTING potato plants did not prove a success with us. Doubtless part of the failure was due to the very unfavorable season.

THERE are still a good many farmers in this country who believe in cooking feed for stock. A dozen of such will describe their practice in next week's RURAL.

WHAT most of all is wanted among blackberries is a thornless variety as good as the best of the old kinds. The Wachusett comes the nearest to this, but it is not sufficiently productive.

THE potato rot seems to have been arrested in the vicinity of the R. G. The potatoes in some fields are a mass of rot and will not be dug. Those left in the soil, however, are rotting rather less than those which were harvested a week or so ago.

BROTHER FARMER, wouldn't it be better to bring that mower in out of the weather? And that reaper? Also that horse-rake? Likewise that lumber-wagon? Ditto that cultivator and harrow? We know the manufacturers are anxious to sell you more implements, but you should look out for your own interest as well as theirs, and no farmer can afford to house his tools under a tree.

FASHION and the "$3-shoe" men have injured the hide and leather trade. If the old style leg boots had not been driven out of form by lighter foot wear, we might still be searching the earth for hides as we were doing 60 years ago. Cut down the amount of leather needed to make a boot by one-half, and at the same time increase the supply of hides, and also the facilities for transporting them, and there can be but one result. The new process of tanning said to have been just discovered by a professor in the University of California will, it is reported, render leather at least five times more durable than it can be rendered by any process previously known. What will become of all the hides when this sort of leather shall be in general use?

Rural Topics.

JERSEYISMS.

YES, it is better to take your $500 or $600 and pay it toward a farm, than to hire a place on shares and use your money to buy cows and horses.

There is no better time of the year for cutting those briars and bushes beside the roads and fences than the present.

A seeding of six pecks of winter rye to the acre is better than the ordinary rule of a "bushel an acre." If you cannot afford that, then do not raise rye.

Did you know that you have some cows that give heavier milk than others, and that if you are butter-making, those are the cows to keep?

Never mind asking how much Farmer So-an-So is worth. You had much better inquire how he made his money and how good a farm he has. That is the test of his "worth."

When do you pay your hired man? It may depend on the man largely, but I like the old way of paying at the close of the season, instead of monthly.

You left your plow out there on the edge of the field last May, but what would you say if your wife left her churn out in the sun an hour or two too long?

Why, of course, you are going to the fair; are you not? If not, why? There is no reason for not going. Hitch up, and be sure to put in two seats, so you can all go.

As to those trees that you think of thinning out next winter, just look at 'em now and mark the decaying ones. You can tell better now than during winter.

Clean out the ditches before the fall rains come. Gather your seeds. Cart in some muck. Do not throw those seeded weeds in the pig-pen, but burn them.

Potatoes to dig; corn to cut and husk; roots to gather; apples to pick! Wake up, my dear fellow! No time to be dull with the year so bright!

When you pull those roots, hadn't you better pull that root of bitterness between you and your neighbor? But, say, what did you let it grow for?

It is not a good plan in the long run to change work frequently with your neighbors. It is very pleasant, but it tends to lounging and idleness.

Hurrah, hurrah, for the premiums! Here's to the girl that can best darn a stocking, and to the lad that shall raise the biggest squash! Are they your children?

You are acquainted with that man who speculates in a little of everything, and turns pennies by shaving notes. Are not you? Then cut his acquaintance forthwith.

Wheat shrinks one-tenth of its first weight inside of eight weeks after it is thrashed in the fall. [?—EDS.] *Ergo*, is it not better not to thrash till winter?

It may not be generally known that seed wheat sown after it is one year old never produces smut. I think this is also true of rye. Who knows?

Mustard may be cultivated with profit. It is sowed two quarts per acre, reaped, thrashed and sweated. The crop is about 25 bushels an acre. It sells at from $2 to $3.

Pay the same attention to the culture of your fruit-trees that you do to your corn potatoes and vegetables, and they will yield seven per cent. more.

If you must divide your farm into fields, have them square. A kit-a-corner field is not economical in any sense, and does not agree with good farming.

The farmer, or the farmer's hired man, who runs to the village every evening, and is not home till 11 o'clock, is cousin to the sluggard.

What? Keep your boy out of school till fall work is done? Don't do it. He is worth more to you in school than picking apples or husking corn. J. E. S.

Westfield, N. J.

BUCEPHALUS BROWN'S NOTIONS AND IDEAS.

DAIRYING is increasing so rapidly all over the country, and the yield per cow has so advanced that American dairymen must soon begin to look out for foreign markets for the butter, as well as their cheese. Here is the true field for the creameries, and they should push forward in that direction, rather than, as Hoard's Dairyman intimates, seek to crowd their goods into families, in competition with the better class of farm dairies. These things must, in the long run, regulate themselves; but much disturbance would be avoided, if more sound thought were given to the matter.

THE HUMAN CONSTITUTION in warm as well as cold countries, demands "respiratory food," and choice edible fats and oils, like butter and olive oil, will always rate as table luxuries, and command fancy prices like favorite wines. Here is a field that opens itself for a vast amount of skilled labor on the farm. Choice butter and cheese, like choice fruit, are products not possible except under trained and specially skillful hands. These are the openings for educated farming, and in them only educated farming will find a profitable success.

EDUCATED FARMING, however, suffers from the confounding of mere literary acquirements with genuine education. This is the reason why "book-farming" has had point as an opprobrious epithet. But a man may have large literary acquirements with very little true education, and, on the other hand, he may be thoroughly educated in many lines without possessing any true literary tastes.

FARMING, properly carried on, offers the best of fields for the all-around development of the human faculties and character. It is not a fenced-in business which few can hope to enter upon. It is open to all industrious men. The poorest boy, if he is strong, bright and energetic, can be the master of a good farm in America by the time he is 30 years old; and that is quite soon enough, for that is as soon as he is likely to know enough to run it. And in what other business are such results so easily acquired?

FAILURE IN FARMING, of which we hear so much, comes, in the great majority of cases, from entering the business without mental capital, quite as much as without money. The wise youth who chooses this line of life will apprentice himself to a good master, know his chosen branch thoroughly, and work as a subordinate until he has gained cash enough to start alone. In doing this he will learn as he goes along, not only how to work, but the amount of means he must have to do it successfully.

IT IS MUCH THE SAME with farmers' wives. Farming should be the favorite business of those women who demand the equality of the sexes in all things; for an educated farm girl will be qualified to be the equal partner of her husband in his business. Here man and wife can work together, each in a sphere of his or her own, of equal importance, and contributing equally to their mutual success I wish that I had the power to convince our young people of the merits of farming as the safest and surest basis for a satisfactory life work. Farming has its trials, and it is a great test of character; but it offers the most and the purest satisfaction that humanity can realize on this earth.

The Vineyard.

REMOVING THE BORDEAUX MIXTURE FROM GRAPES.

M. H. BECKWITH.

IN all that has been written concerning the spraying of grape vines with the Bordeaux Mixture it is claimed that the rains will remove all traces of it by the time the fruit matures. This is contrary to my experience with the grapes upon which the mixture was used the present season. There has been a large amount of rainfall since the final application of the Bordeaux Mixture to the vines in two vineyards where this Station has been testing the efficacy of various solutions for the disease known as the "black rot." The owner of one vineyard in Kent County, has applied the Bordeaux Mixture about every 10 days, under the direction of this station, while some of his neighbors have made only one, or, at most two, applications to their vines. The result is that the vines which have been repeatedly treated are free from the disease and have perfected a fair crop of fruit. Those of his neighbors have the fruit entirely destroyed by the disease. But in the meantime the grapes are more or less covered with the Bordeaux Mixture, rendering them unfit for market. The consequence was his neighbors were inclined to laugh and say to him: "You have saved your fruit; but what good is it to you as it is unmerchantable?"

The owner of the vineyard was of course very greatly discouraged by these remarks and wrote to the director of this station who at once visited the vineyard with the view of devising some method of removing the mixture from the fruit.

Upon trial it was found by adding a small amount of cider vinegar to the water in which the grapes were placed and allowed to remain a few minutes, and afterwards rinsing the fruit in water, the adhering mixture could be entirely removed. The method pursued in this case was to use one quart of strong cider vinegar to five gallons of water. The fruit was placed in wire baskets which would contain about 20 pounds. By using two baskets and placing the second in the vinegar and water when the first was removed, and allowing it to remain there while the first basket of fruit was rinsed twice in water and the grapes spread upon evaporator frames or other receptacles to dry, then the second basket of fruit would be ready for rinsing. Acetic acid could be used if desired instead of the vinegar. The fruit treated in the above manner was rendered perfectly wholesome and merchantable and the expense is light.

Delaware County, Agricultural Experiment Station, Newark, Del.

Pomological.

WYANT PLUM.

THIS fine native variety was favorably spoken of at the nurserymen's convention at Chicago, and a reader of the RURAL asks me to give something about its history and its claims to public attention.

It originated on the grounds of a Mr. Wyant near the small town of Janesville on Cedar River in Iowa, where it has not missed a crop in a number of years. That it is a full-blooded native of the Americana species I have no reason to doubt. In size it does not average larger than the De Soto, and it is much like it in shape and color, its superiority consists in its high quality for dessert or culinary use, and its being a perfect freestone.

Where perfectly ripe specimens are cut up and used with cream and sugar it is superior for table use to any native plum I have tested, and when canned it has very little if any of the usual astringency of our native sorts. In 20 years it has shown no defects in tree, foliage, or habits of regular bearing and it is not troubled with curculio to a greater extent than the De Soto.

At the East it may not do as well, but it is worthy of trial where there is a demand for our best native sorts. J. L. BUDD.

Ames, Iowa.

Farm Economy.

FRUIT EVAPORATING.

THE evaporating of fruit has become one of the new and leading industries of the northern tier of counties in Western New York. The business has grown, in six or eight years, from drying a few pounds of apples or berries to be traded at the store for groceries or dry goods, to a business requiring thousands of dollars to carry it on; in fact, in some towns a good apple crop brings in as much money as all other farm crops combined. The business is well distributed throughout the country, there being comparatively few large evaporators, but a large number of the capacity of from 20 to 100 bushels per day owned by the farmers themselves. The evaporators are of various kinds. In my own work I prefer what is known here as the Box Evaporator. This is simply a box 19 feet long, four feet wide and five feet high, standing on a substantial stone wall. In it are runways for the trays which are 3x4 feet, made of galvanized wire cloth. These are filled with prepared fruit and shoved in directly over the furnace, where they remain 15 minutes, and are replaced by more trays of fresh fruit, the first ones going on the next run above with less heat, and so on until they reach the top and are taken off dry. The fruit remains in the evaporator five hours and I dry 100 bushels per day.

In preparing apples for the evaporator, the machine that pares and cores the apple is generally run by hand, one man or boy paring about 50 bushels in ten hours. The apples drop from the machine on to a table, and bad spots and bits of skin that remain are trimmed off. Then they are taken to the bleacher to be bleached with sulphur smoke, and are then sliced ready to be spread on the trays for drying.

The raising and evaporating of raspberries are receiving a good deal of attention, many tons being evaporated each season. The process is the same as for apples, except as regards the preparation, the berries being ready for the evaporator as they come from the field.

I have just finished evaporating my crop of berries for this season, which was a light one on account of wet weather. B. A. T.

Wolcott, N. Y.

Miscellaneous.

NEW JERSEY NOTES.

The Erie and Lawton Blackberries as we have them, are alike; that is, if the Erie is a seedling, it is no improvement on the Lawton.

The Jersey Tomato is the earliest. The Volunteer is nearly as early as any, and the Beauty, except for earliness, I consider the best for all purposes.

We have one Hawthornden Apple tree. It is a slow grower; in other respects it is similar to the Maiden's Blush, except that the tree is a heavier bearer and the fruit larger. If this is a general characteristic, the Blush should be superseded.

The Northern Spy Potato yielded for us at the rate of 300 bushels per acre. It has two great faults: we have three distinct styles of potatoes from one potato planted, and the eyes are very deep on one of the types. If it is like the old Peachblow, it will always be sprouting.

The Smith's Cider Apple is the tree that bears this year. The Wealthy bears every year and the fruit will be ripe by September 1st. The Lawver is a pretty apple. Our specimen tree appears to say good things come singly. Our tree of Wealthy has for three years borne full crops each year. The Lawver is larger and has not borne a dozen apples yet.

A moist soil that will not stay wet and that seldom gets dry is the place for raising almost any crop suited to the climate. Such land is not abundant and usually sells for less than its value.

The Ott Pear has been very nice this year—about equal to Seckel in quality, and ripe before the Bartlett.

A combination of sheep, poultry and hogs will not keep away the coddling moth, unless the animals keep the ground entirely bare. We have in the chicken-yard a tree on which only one specimen was affected by the worm. Outside where all the stock run the fruit was not much better than was that where no stock went. The kerosene emulsion or the arsenites are effective if properly applied, and they also, I think, destroy the fungus that attacks the little apples and pears.

As a rule, more injury is done by dry weather than by wet. We had a shortage in the water supply for at least seven years out of 10. This year we have had a constant over-supply; but the damage does not compare with that suffered in the dry year of 1880. S. J. H.

CORRESPONDENTS' VIEWS.

FAILURES.—As a rule, people do not like to talk of their failures; much less do they like to have other people speak of them. But I sometimes think it almost as important to know about the failures as about the successes. A few years ago a member of our pomological society stated, in one of the meetings, that he had sold $125 worth of blackberries from a city lot or one-fifth of an acre. Though this had perhaps been often done before, the statement created quite a sensation, and many thought they could do as well and tried it. Had some one in the meeting told how *he had failed* to grow $125 worth, there would have been fewer plowing up their blackberry plantations now to try something more remunerative.

But I started out to write about squash and this is how I grew them—or failed to do so. A rich clover sod of two acres was well prepared, and marked as for corn. Every third hill of every third row was especially manured for the squash. The first row was planted with sweet corn, the next with beans, and the third, except the squash hills, with beans also, and so on. I had raised about 12 tons to the acre on a similar plan, though on somewhat richer ground, and thought to do about as well this year. The squash came up strong, with hardly a missing hill, and grew finely. But, alas! The striped bug made an attack by scores and hundreds. We tried all the known or ever-heard-of remedies, but to no avail. Then we set to killing them—a big job. Hardly had we vanquished them, when the big black stink bug—Anasa tristis—made his appearance. Remedies were again applied, but to no purpose. We killed them by the thousand, but their offensive smell and touch had already done their work and the squash vines withered like Jonah's gourd before the worm. This year we will not have a squash. I once knew how to grow squashes, but I give it up. Next! Please speak in time for next year. W. F. B.

Ann Arbor, Mich.

LARGE YIELDS OF CORN—HOW IT LOOKS ON THE GROUND.—We sometimes see reports

of 150 to 200 bushels per acre. Now let's see about how this corn looks in the field:

With rows four feet wide and hills 20 inches in the drill, three average ears to the hill will give about 185 bushels to the acre. With rows four feet wide, stalks or hills 12 inches in the drill, one ear to the stalk will give 102 bushels per acre, or two good average ears to the stalk will give about 204 bushels to the acre, or 21,624 ears to the acre, which, if shelled, will completely cover one acre of land; and if the variety be the large Southern Shoepeg, (which counts out about 13,000 grains to the bushel) and the grains lie touching each other, it will form a continuous row of grains 166 miles long, or if the corn rows be 2½ feet wide and the ears be laid lengthwise of the rows, every row on the acre will have a continuous line of ears touching each other all over the acre. A yield of 200 bushels on one acre of land will "bread" two families with a husband, wife and six children each, and furnish forage for one cow to each family; or will "bread" a family of five persons and furnish grain and forage for a pair of horses one year. If a South Carolina farmer beats the United States on the best acre of corn this year, our Board of Agriculture has arranged for a premium of $1,000, or $100 will be given for the best acre grown in this State whether the United States is beaten or not.

Anderson County, S. C. J. C. STRIBLING.

FARMING PAYS.—The successful farmer is the one that conducts his farming operations in a prompt, business-like manner. He is the one that never has an ailing animal from the lack of proper care, food and shelter. He is the man that works with his brains as well as his hands. But it is not only this class that makes farming pay, but farming pays the indolent, shiftless farmer better than any other business possibly could. Any other occupation pursued in the same manner would result in utter and complete failure. Although he may do little else but growl, yet he generally manages to make a living by farming, while in any other business he would from necessity become an object of charity.

Watkins, N. Y. C. C.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

WHAT is the proper time to marry? One forlorn maiden sighs: "Whenever you get the opportunity;" but this is looking at the matter in a very frivolous light. The Hospital Magazine says that the best time for the average civilized woman to marry is any time between 24 and 36 years of age. It is not said that no woman should marry earlier or later than either of these ages; but youth and health and vigor are ordinarily at their highest perfection between these two periods. Very early marriages are seldom desirable for girls, and that for many reasons. The brain is immature, the reason is feeble and the character is unformed. The considerations which would prompt a girl to marry at 17 would in many cases have very little weight with her at 24. At 17 she is a child, at 24 a woman. Where a girl has intelligent parents the seven years between 17 and 24 are the period when mind and body are most amenable to wise discipline, and best repay the thought and toil devoted to their development. Before 17 few girls have learned to understand what life is, what discipline is, what duty is. They cannot value what is best, either in the father's wisdom or in the mother's tenderness. When married at that childish period, they are like young recruits taken fresh from the farm and the workshop and hurried off to a long campaign without any period of preliminary drill and training, or like a schoolboy removed from school to a curacy without being sent to the university or to a theological hall. Who can help grieving over a child-wife, especially if she has children and a husband who is an experienced and possibly exacting boy-man? The ardor of his love soon cools; the visionary bliss of her poetical imagination vanishes like the summer mist; there is nothing left but disappointment and wonder that what promised to be so beautiful and long a day should have clouded over almost before sunrise.

Sensible people will agree to this. We know girls who married at 14 and 15; at 30 they are elderly women, too often broken down with illness caused by over-work and too early maturity. These very young marriages are usually among people of small means; they are most prevalent among factory or mill operatives, both here and abroad. Very often the young wife can't even make bread, and it is our fixed opinion that no girl who does not possess a sure income in her own right ought to marry until she is competent to cook a good meal and manage a house.

* * *

WE women certainly can do a good many things well, though the men do not always admit it. We don't always get credit for our cleverness; but a recent writer in the Boston Times gives quite a list of things easy enough to woman, but impossible to man. He says that the average woman can come to a conclusion without the slightest trouble of reasoning on it, and no sane man can do that.

Six of them can talk at once and get along first-rate, and no two men can do that.

She can safely stick 50 pins in her dress while he is getting one under his thumb nail.

She is cool as a cucumber in half a dozen tight dresses and skirts, while a man will sweat and fume and growl in one loose shirt.

She can talk as sweet as peaches and cream to the woman she hates, while two men would be punching each other's head before they had exchanged 10 words.

She can throw a stone with a curve that would be a fortune to a base-ball pitcher.

She can say "no" in such a low voice that it means "yes."

She can sharpen a lead-pencil if you give her plenty of time and plenty of pencils.

She can dance all night in a pair of shoes two sizes too small for her, and enjoy every minute of the time.

She can appreciate a kiss from her husband 75 years after the marriage ceremony is performed.

She can go to church and afterward tell you what every woman in the congregation had on, and in some rare instances can give you some faint idea of what the text was.

She can walk half the night with a colicky baby in her arms without once expressing the desire of murdering the infant.

She can do more in a minute than a man can do in an hour, and do it better.

SOME DAINTY FURNISHING.

THE problem of furnishing a big, bare, country parlor presents itself to many young house-keepers, and there is no doubt that a recent description in the Art Interchange will be of service to such. It combines artistic beauty with economy—not always an easy matter. The parlor furniture described cost, altogether, $50. It was a large room, with six windows. The fireplace was in the middle of the room, so that there were two awkward little passages between the chimney and the wall, which ended in two tall windows. In the center of the floor was a square of dark-blue Canton matting 18 by 22 inches, the remainder being painted ochre yellow. This cost $1 for paint and varnish, and $7 for the matting. The walls were tinted pale yellow, the dado and freize being broad bands of rich, dark-blue paper. The ingenious furnisher then bought a bamboo railing and lined it with blue make-believe India silk—really soft cambric—and put it up over the narrow passages that separated chimney from walls. From this she suspended on rings portières of Japanese silk, having a border of gold worked in conventional figures. They were bought at a bargain for $3, but reduced the awkward size of the room, giving it a graceful irregularity.

There were six tall, many-paned windows, trimmed, first, with plain shades, and then with curtains hung from rattan canes. The curtains hung in straight folds, the sticks being run into the stuff so that half a yard hung over and formed a lambrequin. They were made of straw-colored scrim at five cents a yard, but dainty designs painted on the lambrequin and border showed a wide band of morning-glories, daisies, running vines, Virginia Creeper and trumpet flowers outlined in gaily-colored silks. The center-table was a huge hogshead, its ample form covered with a full petticoat of rich yellow sateen that fell in charming folds on the blue matting. Its top most securely nailed on, held a student's lamp with two burners, the shades of which were both covered with yellow India silk, on which moths and butterflies were painted and outlined in Kensington embroidery.

The book-case was made of three dry-goods boxes, painted black, as least conspicuous (and a rough board will not ebonize); the sides, inside and out, were covered with folds of yellow sateen, tacked in place with gold tacks, and graduating in size, so that it formed a pretty and unique piece of furniture. On top of this book-case stood a huge jar. This had been a bottle-jar of dismal snuff-brown; the artist painted it dark blue, glazed it with varnish, and filled it with golden-rod and wood-lilies, and a background of cat-tails; and then she twined it with the luxuriant Virginia Creeper and trumpet flower whose bell-shaped, ruddy flowers are a delight to color-loving eyes. The great difficulty was in providing sofa and chairs. Thirty-three dollars accomplished this, securing a rattan sofa, two arm-chairs and two rocking-chairs, a little willow rocker at 75 cents, and a couple of stump chairs with rattan backs. The sofa was made a real resting place by covering it entirely with a mattress of cat-tail down. It required three layers of muslin and cat-tails, then a cover of muslin, and then one of light blue denim, through which mattress stitches were taken, fastening it securely to the sofa. The pillows on this sofa are of red, blue, yellow and sage-green linen. A similar cushion was put in each chair.

An upright piano, placed so as to cut off another corner, had a gray linen cover, worked in conventional designs in colored wash silk. In odd corners were three little corner cupboards and cabinets, worth 50 cents each, which were respectively stained in antique oak, in cherry, and enameled white, each with a little China silk curtain on a brass rod, pulled aside to show trifles of bric-a-brac. The fire-place was filled with a mass of gorgeous wild-flowers. On the tall, ungraceful mantel was a mirror its full length, frameless and not of very fine glass; but this did not show. On it, all around the edge, was painted a trailing vine of morning-glory and Virginia Creeper. Books were everywhere, and magazines, and the pretty colored prints that come with first-class art magazines were pinned with easy negligence on the wall, instead of framing. As the Art Interchange describes, it was a charming interior, and one that will suggest ideas to many busy fingers.

VERY HOMELY JOTTINGS.

OLIVE E. DANA.

SOME one told us lately that a good way to improve the looks of pies is to wet the upper surface all over with cold, sweet milk just before putting into the oven. The milk may be applied with a bit of clean cloth, a brush kept for such uses, or the tips of the fingers. I was delighted with the fine glaze the new way gave, and with the delicious brown hue the upper crust, so treated, took.

Cookies and hard ginger-bread get a fine gloss treated in the same way.

The flat, handleless covers of tin lard pails, which accumulate so rapidly, are very handy to hold pie-plates, with pies in them, just taken out of the oven. I keep a stock to serve as pie-holders, and they save soiling shelves and table-cloths.

I have been much troubled ere this with the crusts of custard and pumpkin-pies. They would sometimes break around the rim, when the crust was built up, and for no apparent reason. I tried a suggestion of Adelaide Cilly Waldren, in the "Cozy Corner" of "Good Housekeeping," with good success. She advises exposing the crust, adjusted to the plate and ready for filling, to a current of cold, dry air for some minutes. Try it!

If you haven't a fine, japanned cake box, and find that an earthern jar or any other tight receptacle makes the frosting melt, try a new paste-board one, of convenient size, and lined with fresh paper. In a cool, dry, dark place it serves very well for a short time. I have found, too, that an apple or two placed in the cake-box or jar seem to help keep the cake from drying. But ordinary sorts of cake, it seems to me are much better eaten at once or within two or three days at longest. It is better to bake less and oftener.

An excellent relish for breakfast or tea may be had from any cold corn left from dinner. Cut the corn from the cob, and put into a saucepan with milk enough to cover the corn and a little more for broth. Add a little butter, salt and pepper; let it come to a boil, and serve hot.

Another good relish for breakfast, dinner, or even tea, with cold meat, is made of either green or ripe tomatoes. Wipe the tomatoes caretully with, first, a wet and then a dry cloth and cut out all specks. Slice rather thinly, and put over the fire in a granite or porcelain stew-pan with equal parts of vinegar and water to cover them. Cook till nearly tender enough to eat, then drain, add vinegar to cover, a little butter, salt and pepper, and simmer again some minutes. May be used warm or cold, but is better quite cold.

Probably horses, especially while in the stable, suffer more than people do in fly-time. Some very serviceable though homely fly-blankets may be made of shirts, bags, or any other coarse, thin bagging. Take two similar bags, cut out the seam of each so as to leave a rather long piece, sew together very firmly the longest way, and hem the edges. We used for thread twine such as comes around grocery-parcels, and threaded it into a darning-needle. Sew straps of the strongest material at your command in the usual places, and see if you have not provided for stable use a grateful protection for the poor, worried horses.

GOLDEN GRAINS.

LYMAN ABBOTT says that if a man builds, Nature straightway sets to work to undo his building. Rust eats into the iron and decay into the wood, and little by little time ravages and destroys. But if a man plants, Nature proceeds to complete his unfinished work. He sows a seed, and behold wheat; he plants a cutting, and behold a tree. Such is the difference between working alone and working with God.....

IN preaching, said Beecher, never turn aside from a laugh any more than you would from a cry. If mirth comes up naturally, do not stifle it; strike that chord, and particularly if you want to make an audience weep. If I make them laugh, I do not thank anybody for the next move: I will make them cry. Did you ever see a woman carrying a pan of milk quite full, and it slops over on one side, that it did not immediately slop over on the other also? .....

WHERE is the use of the lips' red charm,
The heaven of hair, the pride of the brow,
And the blood that blues the inside arm,
Unless we turn, as the soul knows how,
The earthly gift to an end divine?
—*Robert Browning.*

THE CHRISTIAN INQUIRER says that many a man can show resignation in a great bereavement, whose daily life is in large part devoted to grumbling over the little ills of life.....

THE CHRISTIAN UNION says that he who has a well-defined purpose in life finds that all his time and all his energies are not too much to devote to that purpose. He who lacks such a purpose knows nothing of the true enjoyment of life. What are you living for? If you cannot answer that question, your life is a failure.....

"As we meet and touch each day,
The many travelers on our way,
Let every such brief contact be
A glorious, helpful ministry;
The contact of the soil and seed,
Each giving to the other's need,
Each helping on the other's best,
And blessing each as well as blest."
—*Coolidge.*

NOTHING under a thorough change will suffice, says Robert Southey; neither tears nor trouble of mind, neither good desires nor intentions, nor yet the relinquishment of some sins, nor the performance of some good works will avail anything, but a new "creature," a word that comprehends more in it than words can well express; and perhaps after all that can be said of it, never thoroughly to be understood by what a man hears from others, but by what he must feel within himself.....

THE LONDON DAILY NEWS tells this interesting anecdote in a sketch of the late Laura Bridgman: "When Carlyle impertinently asked, 'What great or noble thing has America ever done?' somebody replied, 'She has produced a girl, deaf, dumb, and blind from infancy, who, from her own earnings, has sent a barrel of flour to the starving subjects of Great Britian in Ireland.'".....

Domestic Economy

CONDUCTED BY MRS. AGNES E. M. CARMAN.

"THIS life is not all sunshine,
Nor is it yet all showers,
But storms and calms alternate
As thorns among the flowers.
And while we seek the roses,
The thorns full oft we scan,
Still let us though they wound us,
Be happy as we can."

AROUND THE HOUSE.

ANNIE L. JACK.

"AND the rain descended." Steadily since the first few weeks of spring the rain has fallen, and hay, grain, fruit and

Miscellaneous Advertising.

When Baby was sick, we gave her Castoria
When she was a Child, she cried for Castoria
When she became Miss, she clung to Castoria
When she had Children she gave them Castoria

everything else have suffered. We find the weeds grow faster than ever before "around the house" and friends from a distance look with eyes of sympathy upon our ruined hopes. The philosophy of thorough underdraining was never better exemplified, and we thought the man who could invent a *cheap* and successful hay-tedder would have made his fortune.

Beans have rusted before filling; peas and everything else that could mildew have suffered in that way. "The rain it raineth every day," and warm unhealthful days are a part of the routine. Well it is, if all the eggs are not in one basket, and by having a variety we may hope to save something. For instance, ducks without any trouble, thrive in this moist atmosphere when once they are half grown. How they revel in the puddles and find rich nourishment in a mysterious way among the mud that fills every furrow and ditch. So, though the apples spot, the grapes rot off, and corn has no ears, the ducks and sage and savory remain; we will not despair—some time the bow will come in the heavens again for the eternal promise remains.

But these enforced days of, not idleness but cessation from the routine of labor, make holidays out of the question in fine weather; for the work must go on night and day if ever there comes sunshine enough to dry the hay. One of our family suggests a rainy-day slate where the boys and girls can set down needful work to be done at such times, for one is apt to forget.

The RURAL very sensibly advocates holidays for farmers and their families, and I am often obliged to think how much they need some pleasant recreation amid the hurry; but how seldom they are able to take it. The necessity of making hay while the sun shines is apt to make "Jack" a dull boy, and he and "Jill" look with some envy on the summer residents who spend the season of flowers and sunshine without any need to labor by the sweat of their brow, and so Jack and Jill try to rise in the social scale, as they view it, and to seek an easier life by going "up the hill," only to find that there are thorns and tumbles on every path, and that a brief holiday means but little, and if the farmer's life is not without its cares, it is at least peaceful and wholesome. A friend who has just left me, looking over the past and thinking of my life in its varied aspects, said she could never think of anything but Whittier's line: "Health and quiet and loving words." How much to be thankful for does not this line mean? How what it speaks of out-weighs many wordly advantages and seems restful to every tired heart. "Come unto me and I will give you rest," is the promise given long ago, and amid all the hurry of country life, in hours of over-work, losses and anxieties, there are hours of peace, of quiet gladness, of repose to the tired body and spirit, that no other life affords.

"*Next to the weakness of making excuses is the weakness of accepting them.*"

A MAN'S REVERIES.

AN ancient philospher once said that if ideas were like hazel-nuts he could pound them into some people's heads with a hammer; but being otherwise, it became an impossibility to make one penetrate the heads of some people. The same condition still exists. When I invaded the sanctity of Domestic Economy in order to wage war against the vagaries of one of its contributors, I well understood the necessity of having my scalp tightly fastened on, and although I have been clawed a little, still "I bob up serenely."

Charity pays her respects to me in a seriocomical hysterical manner that completely gives her away. When Charity began writing for the RURAL nearly six years ago, her brothers were grown up; now Burt is still a boy—a remarkable slip in the cogs of the wheel of old Father Time. It is not every one who is favored to such a degree. I do not censure her for her aspirations and longings—only for her abuse of the columns of the RURAL. If she wants to prate to her neighbors, I don't care a picayune. A city man would not dare to create a nuisance because of the law, while a city girl would not make herself a nuisance by rushing into print with a long rigmarole like some of Charity's letters.

So Burt has been away to school?

Well, if his deportment at all corresponds with his sister's description—as, of course, it must—then the sooner that school is razed to its foundations and the professors and teachers are put at work on the roads, the better it will be for all concerned. The letter in which she tells us this puzzles me very much. I did take Burt to be real; but I am now constrained to think him imaginary, for it appears that he and his father are aware of and encourage Charity's peculiar system of amending their manners and morals. So Burt must be a common name for all country boors, and Charity expects to give a powerful impetus to the cause of culture by "whipping the devil around a stump," as it were. Then comes haunting doubt which suggests that, after all, her exhibitions of home life may be the results of a streak of harmless lunacy that runs through the family.

Geraldine Germane looks on the sentimental side of Charity's complaints and applauds. If she will take the trouble to think, even though she may not be used to it, she will probably fail to find any instance of reformation through the means Charity uses. Charity's own reveries furnish proof enough. Burt has been to school, and after six years or more of Charity's companionship, is still boorish and altogether unlovely. Six years of Charity's reveries in the RURAL and a longer intimate companionship have failed to improve or reform her father, according to her own evidence. The chances are decidedly against such vaporings having any good effect, and I think it is time to make a change. Whatever may be the consequence, I shall, in regard to such nuisances, act upon the advice of the Irishman at Donnybrook fair, "Wherever you see a head, hit it," and I will.

A MAN.

Are the flannel garments intended for the first cool weather in wearing order?

EXTRACT FROM A PRIVATE LETTER.

"I wish all the readers of the R. N.-Y. could have the chance to visit the old town of Marblehead, Mass., of which Mary Wager-Fisher has given such an interesting description. Having recently sniffed the salt breezes there and watched one of the yacht races for which the place is noted, I have taken special pleasure in her letters. It would be hard indeed to find a more attractive place for a mid-summer outing than the country all along the rock-bound coast of the Old Bay State.

One thing has surprised me, and that is, the apparent fertility of these so-called poor or worn-out lands. It is true that the rain-fall has been unusual this year, which may, in part, explain the luxuriant growth of every sort of garden product. The hay crop would have been of immense value only for the wet weather, which interrupted cutting and curing; yet, even as it is, the barns are overflowing. Such wide barns they are, too, and so many cattle are feeding on the beautiful hillsides, and such roomy old as well as new houses are seen on either side as one drives from one pretty village to another. It seems as if farming must pay fairly well in this section. Sleek horses, trim wagons, comfortable phaetons and carriages seem to be the rule, and well-dressed, healthy-looking men, women and children are seen driving over the excellent roads. Even the side-walks of the villages are well kept. And the country church has its never-failing and artistic decorations of the prevailing blossoms of the season. Really there seems no need to commiserate either the farmer or his family, or to "Go West" while the East offers so much comfort at the very door.

With my lines fallen in such pleasant places, I had leisure to observe the ways of the housekeepers hereabouts. One innovation I accept—in spite of a strong prejucice against it at first—that is, using a wet cloth instead of a broom for the weekly cleaning. For bed rooms and sitting-rooms it works like a charm and the work is not any harder than sweeping, while the dust is almost entirely avoided. Take a clean pail of water with a little salt to help keep the color; wring a soft cloth very dry frequently and wipe the floor or carpet or matting, and the effect is wonderful. There seems to be a permanent cleanness that never results from the use of a broom, while all the flying particles which usually cover furniture, pictures and all projections, are entirely avoided. Then think of the saving to delicate throats and lungs! Try it and see if fact will not conquer prejudice.

If there were time and space a tale might be told of the wonderful result of planting two rows of potatoes according to the trench method. Certainly I was surprised myself and the owners who did not advise the planting of the tubers at all, in consequence of frequent failures on the sterile soil, were quite willing to admit the success of the new way, while I regretted many times that we didn't plant the whole farm to potatoes, and we all might feel the same regret only for the rot which has begun already upon our small plot and upon our neighbors' larger ones. So we say again: "The trail of the serpent is over it all" and accept the inevitable as cheerfully as possible.

A. R. D.

WE do not think ground floors desirable as sleeping apartments. Neither do we think that night air should be allowed to blow directly over the sleeper. These are precautions against sickness that we would by no means confine to malarial districts, but are such as we follow whether we are by the sea or in the mountain.

CORN FRITTERS.

A PINT of grated corn—it should be tender—one beaten egg, half a tea-cupful of milk, salt, half a tea-spoonful of baking powder and about two-thirds of a tea-cupful of flour—a little more may be required. Beat together and fry in spoonfuls in a little hot beef drippings or butter. Very nice as a breakfast dish.

CHICKEN COOKED IN MILK

SELECT tender spring chickens. Dress and cut into suitable pieces for serving. Cook in milk and water—one quart of milk and one cup of water—until tender. Season, add a large lump of butter, a cup of cream and a little corn starch made smooth in a small quantity of milk for thickening. Serve on toast if liked.

FROZEN PUDDING.

ONE pint of cream, three pints of milk, five eggs, three cups of sugar, a pint of ripe peaches cut into small pieces. Put the milk into a dish set in a kettle of boiling water. When very hot, add sugar and yelks of eggs, beaten, then the whipped whites and stir until a thick custard. Turn out and when perfectly cold beat in the cream. Freeze until quite stiff, remove the dasher and stir in the fruit. Cover and serve in an hour.

MRS. ECONOMY.

TOMATO PRESERVES.

FIVE pounds of yellow egg tomatoes, five pounds of white sugar, juice of two or three lemons. Cover the fruit with the sugar, and let stand over-night. In the morning, drain the sirup from the fruit, boil, skim, put in the tomatoes and boil very slowly 20 minutes. Skim the fruit out into plates, boil the juice until quite thick, adding the lemon juice just before taking off. Put the tomatoes carefully into bottles, and cover with the hot sirup. Seal at once.

News of the Week.

HOME NEWS.

SATURDAY, September 7, 1889.

THE combined Farmers' Wheel and Farmers' Alliance of Missouri, in joint convention, favor the placing of a tariff on the luxuries, instead of the necessaries of life and a gradual reduction of the tariff, which shall ultimately lead to free trade. Missouri is, of course, strongly Democratic .....Canadians are still angrily indignant at the indifference of the Mother Country to the Behring Sea troubles, no reference to which occurred in the Queen's speech recently read on the prorogation of Parliament. A friendly conference of the maritime powers is likely to be held on the matter. Meanwhile the Rush and her sister cruiser are capturing an occasional Canadian poacher, taking the arms, salt and seal-skins out of her and either "paroling" her to go to Sitka or sending her there under a prize crew of one. In a few cases the vessels have gone there; in all the others they have either gone to British Columbia for fresh supplies and sometimes returned to the sealing ground, or straightway begun seal-catching as soon as out of sight of the "confounded Yankee." ..... Chicago is still trying to get fit men for the Cronin jury; but it appears a mighty hard task to find them. Germans and Irish are to be excluded, and so are all among the remaining remnant of the Windy City's population, who are intelligent enough to have formed a decided opinion on any subject bearing on the murder. Still it is hoped to secure 12 good men and true among "native Americans" to try the case intelligently and impartially..... ..It is now considered improbable that there will be an extra session of Congress..... ..... Loud complaints still come from the Conemaugh Valley about the dilatoriness and incapacity of the Flood Commissioners. There is little doubt that their action and the complaints to which it has given rise, will have a stunting effect on public charity in the case of any future great calamity ..... Legitime, having at last been driven from Port-au-Prince, Havti, went on board a French man-of-war from which he shipped on the American steamer Manhattan, and arrived here Thursday with his family, 22 trunks, several officers and three terriers, He goes to France to-day, and will remain their some time. Hippolyte entered Port-au-Prince peacefully and no vindictive executions have since occurred. The commanders of the United States and other foreign war vessels as well as the consuls interfered vigorously against any violence..... ..... Several fatal accidents have occurred within the week from contact of men with electric-lighting wires, notably in this city and Buffalo, and minor accidents from the same cause are frequent.. ..... Each of the constitutions of the five new States in one form or another recognizes the right of women to the suffrage. North Dakota, South Dakota, Idaho and Washington have each granted school suffrage to adults of that sex; Montana gives them the right to vote on local questions provided they are tax-payers, while Washington and South Dakota will submit the question of unrestricted woman suffrage to the voters. This action may help to add to the scant feminine population of those pioneer parts of the mighty Union..... ..... Race troubles have broken out in several parts of the South during the week. Near Algiers, across the Mississippi from New Orleans, shots were fired into a train-load of colored excursionists and a bad stampede followed. One "nigger" killed and several others more or less seriously injured. A "colored" church was also cremated by the whites, which is bitterly denounced by the New Orleans papers... .....At Shell Mound, Le Flore County, Miss., a serious conflict between whites and blacks was threatened. The latter were at first six to one; but did nothing. White militia and volunteers flocking from all the surrounding country soon reversed the disproportion, and at last accounts the chief black malcontents were surrounded. Four of them have been shot while resisting arrest and 40 other swamp fugitives since then...There is also much anxiety in Red River Valley, West Virginia, at the prospect of a race war due to trouble between a white store-keeper and a colored customer. With growing frequency, wherever such troubles arise, there is a tendency to take sides, not according to the merits of the case, but according to the race of the contestants. The negroes are becoming more enlightened and less dependent, and often more outspoken or "insolent," and the whites are as determined as ever that a "nigger" must be subordinate and obsequious. Of course, many individuals and even communities are exceptions to this rule, however..... A $100,000 bar of gold, the largest ever cast, was turned out at the Helena, Mon. Assay Office on Wednesday..... A big Coke Trust, to include 1,500 ovens, is in course of formation at the head-center of the coke trade about Connellsville, Pa.....There's little that is new about the great World's Fair. The Site Committee here is still hunting for the most suitable site; the Finance Committee appears languidly waiting till a choice is made; the other committees are partly in Europe, partly in the country and wholly inactive—as yet. Chicago is bustling about in quite a lively fashion puffing her own claims, belittling those of other places, trying to get every convention and caucus to indorse her, and steadily raising money. As she has lately taken within her limits many large farms and a wide sweep of prairie, there should be no difficulty about a suitable site. Washington is sleepily waiting for the meeting of Congress, and St. Louis and the other claimants are doing nothing except talking now and then..... The coal miners of Northern Illinois who have been locked out since April, and who were threatened a week ago with a permanent stoppage of work, are going to work again, a compromise having been made by all the mine-owners except W. L. Scott, the many-times-millionaire and Pennsylvania ex-Congressman, who still insists on keeping his men's noses pressed hard on the grindstone..... The late suppression of forest fires by heavy rains in Montana appears to have been only partial and temporary, as they are again raging with old-time impetuosity. The destruction of timber has been immense..... Drake Carter, the Toronto race-horse whose record of 5.24 for three miles, a few years ago, has never been beaten, fell and broke a leg while training a week ago, and had to be shot..... .... The westward march of civilization has been marked by the successive establishment and abandonment of new army posts. Fort Laramie, Wyoming; Fort Lyon, Colorado, and Fort Hayes, Kansas, were abandoned the other day.....The latest reports from the part of Sioux Reservation lately thrown open to settlement, say there's nothing of an Eldorado or Garden of Eden about it. One-third of it belongs to the "bad lands" and most of the rest is said to be a vast, rolling prairie with a rough sod covered with sage brush, cut here and there by sluggish streams that run in gulleys, which have the appearance of cracks in half-baked brick. Better "go slow" in selling the old homestead to take up a new one in the Land of the Sioux..... ..There is no prospect that the Cherokee Nation will, in the near future, consent to the sale of the Cherokee Strip. The other Indian tribes, who are far less civilized and much more influenced by white men, are willing enough to sell their surplus lands; but the Cherokees, who are about as civilized as their white neighbors, have a business-like desire to make all they can out of their possessions. Ex-speaker Carlisle, however, thinks Congress may summarily take the land at a fair figure during the next session, as the title to it is seriously in dispute .....The British law officers have just decided that the Jesuit Endowment Act, passed over a year ago by the legislature of Province of Quebec, and which has caused such a bitter rumpus between Protestants and Catholics in Canada, is constitutional. That legally settles the matter, as the year within which the Governor-General could constitutionally "disallow" or "veto" the act, has passed. The bitterness engendered by it will, however, rankle for years in Canadian politics....There are now over 14,000 Icelandic settlers in Manitoba and the Canadian Northwest and more are coming..... .....The Prohibitionists of Massachusetts have nominated a State ticket and declared war on the Republicans, because their party permitted the defeat of the prohibitory amendment to the constitution at the last election. The Democratic Party, however, was solidly against it; but rancor against a recusant friend is hotter than against an acknowledged foe..... Last Sunday Carlisle D. Graham, the Philadelphia cooper who has been riding in a barrel boat at intervals for nearly a year in Niagara River, just below the Falls, went over the center of the Horse-shoe Fall, on the Canadian side, early last Sunday morning. He was stayed and packed in the barrel-boat, to the bottom of which 100 pounds of railroad iron were fastened to keep it upright. The plunge was 159 feet, though some put it up to 200. He was released from the barrel in a semi-conscious condition, but is now all right and ready to do it again "for money." He's the first man that ever went over the Falls and lived to tell the tale ... . Dr. Samuel A. Allibone, author of "Dictionary of Authors," of late years Librarian of the great Lenox Library in this city, died last Monday at Lucerne, Switzerland..... ...The greatest horse race of the year, so far as the value of the stakes is concerned, occurred near here, at Sheepshead Bay, Long Island, last Wednesday. It was the Futurity race for two-year-old colts and fillies, won last year—the first of its establishment—by the Kentucky horse Proctor Knott, which has since grievously disappointed the great expectations then formed about him. Course, three quarters of a mile; time, 1.16 4-5; value of the stakes $61,000, with about $6,000 to the second and $2,500 to the third. The winner was the gelding Chaos, owned by Ex-Congressman W. L. Scott, the great millionaire iron king of Pennsylvania and coal-monger of Northern Illinois. The time was slow. Chaos stood 9 to 1 in the betting, five being ahead of him. Of late years the race-horse appears to be distancing the trotter in public interest. The three best two-year-olds of the year, with El Rio Rey at the forefront, were not entered for the race .... There appears to be a mistake about the educational facilities in the South. The New Orleans Times-Democrat shows that while the money for Southern schools is nearly all contributed by whites, the average payment for school purposes in the South is greater than in the New England or Middle States. For example: Pennsylvania pays 32 cents on the $100 for school purposes, while the South averages 50 cents per $100—Virginia paying 46 cents per $100: Florida, 59; Arkansas 60; West Virginia, 61; Missouri, 62: Mississippi, 65 Since the war $37,000,000 have been contributed for schools intended exclusively for colored people.....Dandy, Gen. Custer's famous charger, is dead..... ..... Dr. Brown-Sequard's "Elixir of life" craze is rapidly going to join the "blue-glass" craze, the "sun-bath "craze, and the numerous other kindred crazes that have beguiled man with the hope of repulsing Death for a while or baffling him altogether. Several thousand old and ailing men have received the hypodermic injections, and while in some cases temporary good effects were obtained, in most cases no very sensible results followed; while in some instances disease and, in a few, death ensued from blood poisoning. In view of the extreme care needed to obtain a strictly pure and health ul article, and the ignorance, unpreparedness and carelessness of many of the doctors eager to advertise themselves by administering the "cure-all," the wonder is that more "accidents" haven't occurred. With careful and skillful use, the thing may hereafter be of considerable use in medical practice; but the idea that it is of any great value appears to be dynamited. By the way, among all the "subjects" experimented on, not a single "woman" case is on record..... Within a fortnight lately $17,000,000 were scattered abroad from the National Treasury in the purchase of bonds, to help in handling and "moving" the crops.....From June 30 to September 1 the public debt had increased $7,094,003.76. The increase is attributed chiefly to the heavy drafts for pensions..... Labor Day was generally celebrated among the working classes from choice and other classes from necessity last Monday in the labor centers of most of the Northern States. The people, more than usual, rested themselves in country places instead of tiring themselves by useless parading. The day's rest was objected to as wasteful chiefly by those who think a month's rest essential for their own health.....

Nature's Simplicity.

When Nature does a simple thing she arouses wonder, because that which with us, is difficult or impossible, with her, is an achievement of ease.

The inference from this is to get near to Nature's heart. Act in harmony with her kindly mood.

This is precisely the effect of Compound Oxygen as administered by DRS. STARKEY & PALEN, and here are some witnesses who testify to its value:

GLASGOW, KY.
"I regard Compound Oxygen as a wonderful remedy and shall ever be grateful to you for it." JAS. B. MARTIN.

MIDDLETOWN, N. Y., Jan. 25, 1888.
"I have used the Compound Oxygen now for about three years, and consider it the most effective remedy ever offered to the sufferer." REV. WM. MCGLATHERY.

SUMTER, S. C.
"I have used the compound Oxygen Home Treatment from DRS. STARKEY & PALEN, as a revitalizer, and have experienced marked benefit from it." MR. N. G. OSTEEN.
Proprietor Watchman and Southern.

SUMTER, S. C., March 17, 1888.
Mr. N. G. Osteen adds in letter of later date:
"Your remedy is getting up quite a reputation in this vicinity from the good it has done Mr. Charles Witherspoon."

We publish a brochure of 200 pages, regarding the effect of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia: all chronic and nervous disorders. It will be sent, free of charge, to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa., or 120 Sutter Street, San Francisco, Cal.—*Adv.*

FOREIGN NEWS.

SATURDAY, September 7, 1889.

The strike of London stock laborers still continues and has grown to enormous proportions. The loading and unloading of vessels in the Thames are conducted by the great dock companies, which own vast inclosed docks, like St. Catherine's; by the warfingers who load and unload on the stone embankments along the river sides, and by lighters which bring and carry cargoes from and to ships at anchor in the stream. The first does much the largest business, and the last much the smallest. All employ regular hands at so much a week, and many more "irregulars" at so much per hour. The latter in the docks, to the number of about 2,500, were the first to strike. They wanted 12 cents per hour, and at least four hours' work a day. Warfingermen and lighter-men soon joined them, and so did all the hands working along the river; then came the carters, coal-heavers and all other laboring people in any way connected with the river business. Soon factories could not get coal and had to stop; other kinds of workshops could not get supplies and had to shut down, and in a few days over 150,000 laboring men either went or were forced into idleness. Contributions poured in for their support; great sympathy was expressed for them by the public; they paraded and loitered, but kept wonderfully quiet. All perishable goods on vessels in the river were ruined. Cargoes of sugar couldn't be marketed and prices went up; a coal famine set in; 250 steamers and a vast number of sailing vessels lay compulsorily idle under heavy expenses; certain lines of business became hampered and then paralyzed, and enormous losses were incurred..... A large number of vessels went to Southampton and other ports to be loaded and unloaded. Dockmen at Liverpool, Glasgow and other ports, who threatened to strike, got their demands; labor unions in Belgium and elsewhere refused to allow workmen to go to fill the strikers' places, but contributed to the support of the latter, money having been sent from this country and as far off as Australia. Efforts to compromise the trouble failed Many ports in the United Kingdom and other countries are now suffering on account of the strike. Vessels and goods that ought to bring wealth and give employment are idle in the Thames. Over 150 stevedores are, on this account, idle here, and 70 in Boston, and in European ports the case is worse. The men openly declare that if their demands are now granted, they will increase them on the first opportunity. Many classes of workingmen all over the country have either threatened to strike for higher wages or done so, In most cases their demands have been either granted in full or compromised. It is the greatest European peaceable labor uprising on record. As large a one occurred in Germany some months ago, but it was attended with much rioting, destruction of property, blood-shed and death, the military and mobs coming into frequent collision. Some of the warfingers have "caved in," and over 2,000 of their men have gone back to work. Ship-owners, merchants and the general public urge a settlement of the trouble by granting the men's demands; but the dock millionaire owners are still obdurate. It is expected, however, that they will soon yield.....

AGRICULTURAL NEWS.

SATURDAY, September 7, 1889.

THE Senatorial Committee headed by Senator Vest, has been inquiring into the value of Chicago's meat products, and their transportation. There has been a steady decline in the prices of beef cattle for a number of years, without any decrease in prices of meats. An Elgin dealer said that dealers throughout the country bought Chicago dressed beef in preference to buying live stock. The freight tariff is higher on live stock than on dressed beef, hence small dealers buy the latter, and leave Chicago to control the live stock market. E. T. Jefferey, general manager of the Illinois Central Railroad, admitted that the prices charged for delivering live beef were greater than for dressed beef. A young man who had been in the employ of Nelson Morris for three years previous to last May, testified that his firm and three others formed a combination, and regulated the price of cut beef in seven States. Several prominent dressed beef shippers who had been summoned as witnesses did not obey the summons, among them Swift and Armour. Certain papers and lists that were called for were also not forthcoming. A resolution was adopted that the facts of the refusal of these parties to appear be reported to the chairman of the United States Senate at its next session. Armour says he would not appear because he knew he could not expect fair treatment from Senator Vest, who is opposed to the dressed beef business..... An association of orange dealers was formed in this city during the week, the object of which is declared to be to unite with the growers and so stop the shipping of oranges to irresponsible persons who undersell the other dealers. Representatives were present from all the principal Northern cities, and from Jacksonville, Florida. The Florida growers were reported to be anxious to have responsible dealers come down there and buy the crop. The movement is probably a step toward the selling of the orange crop at auction .....

Supplied with artesian well water equal to Waukesha water. For society, church and school advantages is unsurpassed. Apply to
FRANK THORNBURG, Clinton, Iowa.

INVEST YOUR SAVINGS.

The Nebraska Mortgage and Investment Co.,
FREMONT, NEBRASKA.
Paid up Capital, $250,000.
We seek safe investments for our customers rather than high rates.
We offer 6½ per cent. loans guaranteed, 7 per cent. unguaranteed. Interest payable at Kountze Bros., 10 Broadway, N. Y City, the day it is due. Loans are selected by us with the greatest care, and based upon the most conservative valuations. Its managers have had fifteen years' experience: having handled fully three millions without the loss of one dollar to their investors. We make a specialty of procuring large or small amounts of gilt-edge short-time paper, running three to twelve months, for savings banks and others. Payment guaranteed. Correspondence solicited. References on application. See advertisement in Harper's Magazine for October.
GEO. W. E. DORSEY, President.
C. H. TONCRAY, Vice-President and Manager.

Buffalo's great international fair opened for the second season on Tuesday morning, with an immense crowd in attendance. It was Childrens' Day, all children being admitted free, and the grounds were packed with them. The exhibition is said to exceed that of last year, the live-stock show being the finest ever seen in this country. There are over 2,000 head of sheep on exhibition. The Northern Pacific Railroad Company has an exhibit of the productions along its lines. The fair remains open until the 13th inst..... The Massachusetts Horticultural Society will hold its next Annual Exhibition at Boston, September 17—20 ... .Several firms of seedsmen in different parts of the country have gone, or are going out of business. The business is evidently overdone.....A Chicago man is said to have a one-third interest in 5,000 tons of dried apples in store near Niagara Falls. They cost 2½ cents per pound, and are being held for 10 cents ..... London dealers report that American apples arriving there are of poor quality and in bad condition. At sales held September 3, Tompkins Kings brought 18 to 20 shillings, Greenings, 12 to 13 shillings, and Baldwins 12 to 14 shillings, for sound fruit..... Linseed oil crushers are receiving large quantities of Western seed.....The Ohio Association of Wool-growers objects to a lower tariff being fixed on wool by New England manufacturers..... Numerous cattle are dying of a strange disease in the vicinity of Carthage, Ill. The animals become stiff in the hindquarters, sink suddenly to the ground and die in great agony.....The Miami Company's elevator was burned on Monday morning with a lot of hay and 35,000 bushels of oats..... The prediction is made that in 10 years a Delaware peach will be as rare a thing in the market as it was 30 years ago. There are now no peaches grown about Delaware City; the peach belt has moved south on the peninsula. Within the past 10 years peaches have become a precarious crop. The yellows is responsible for this. The average crop which, a few years ago was more than 3,000,000 baskets, is now less than 1,000,000. The peach crop of the Delaware and Maryland Peninsula has for the past 20 years been worth more than $2,000,000 a year; the Delaware railroad in 22 years has shipped over 37,000,000 baskets of fruit, and fully half as much more has gone by other routes. Of such importance is this subject, that the United States Government has detailed a special agent to study peach culture in the hope that something may be done to stop the ravages of the disease. The yellows also prevails throughout New Jersey, Pennsylvania, Michigan and other peach-growing States....

FIVE HARVEST EXCURSIONS.

THE Burlington Route, C., B. & Q. R. R., will sell, on Tuesday, August 6th and 20th, September 10th and 24th, and October 8th, Harvest Excursion Tickets at *Half Rates* to points in the Farming Regions of the West, Southwest and Northwest. Limit 30 days. For circular giving details concerning Tickets, rates, time of trains, etc., and for descriptive land folder, call on your ticket agent, or address P. S. EUSTIS, Gen'l Pass. and Ticket Agent, Chicago, Ill.—*Adv.*

Crops & Markets.

SATURDAY, September 7, 1889.

THE weather throughout the most of the country has been dry during the past week which has been very favorable for thrashing and marketing grain. Winter wheat has turned out very well, although there is a great deal of wheat of poor quality. Spring wheat thrashing has but just commenced, but the crop seems to be turning out very satisfactorily. Oats are turning out well. Prices of all grains show little change except as they are fluctuated by local conditions. Grain seems to be moving quite rapidly, besides the local millers are taking large quantities, as the stocks of wheat and flour of many of them were very low. Reports from Chicago say that this week promises to go on record as the heaviest in the amount of grain shipped since there was a lake marine. Tuesday's list of 30 vessels with a capacity of 1,500,000 bushels is at the top. Wednesday 800,000 bushels were chartered. These great fleets carrying 1,000,000 bushels a day to lower lake ports have come in the usual order of traffic and without seriously affecting other lines. They show better than figures can do the capacity of the lake marine of to-day.

THE last two weeks have given the corn crop a big boost, and in some parts of the corn belt, it has been the first really good corn weather since the crop was planted. The condition has improved quite generally, but in spite of this, reports from some States show quite a decline from previous reports. The Illinois crop, according to the State Board of Agriculture, will be 70,000,000 bushels less than reported one month before. Iowa's yield will be from 10 to 15 per cent. less than previous estimates. The quality of the corn will probably vary considerably. The weather is reported very dry in some localities so that the ears may not fill out properly.

THE hop harvest is progressing rapidly, and the yield and quality vary greatly in different localities. Through Central and Northern New York some yards are entirely worthless, while others will yield a full crop. The latest estimates from this section give three-fourths of a crop as the probable yield. Several carloads of California hops were sold in this city during the week; they were of good quality and sold readily at good prices.

CHEESE has declined slightly in price at the different markets in Northern New York, still the sales have been quite large. Many factory-men are holding back for higher prices. Sales at Utica ranged from 7¼ to 8¼ cents, the bulk selling for about 7½ Little Falls sales average about the same. Canton sales were made at 8½ to 9¼ cents, the latter price being for sage cheese made on contract. The butter market is weak, and there is no call for anything but the best grades.

MAGAZINE REVIEWS.

LIPPINCOTT'S MAGAZINE for September contains a clear description of "The Australian Ballot System," which has created so much discussion in this country, and has served as a model for numerous ballot reform bills introduced in different State legislatures. Australia took the lead in reforming abuses existing in all the British colonies under the old system of *viva voce* voting. Francis S. Dutton, of the South Australia Legislature after several years of agitation, introduced a bill at the session of 1857-58, which, after some modifications, became a law. The system has spread all over Australia, and has extended to Europe and America. It has never been discarded by any community that has tried it. Briefly, its provisions are as follows: All nominations are received by a designated officer at a fixed time before each election, and the names of all candidates are posted and advertised at the public cost. The ballots are printed by the State or local government, are all alike, and contain the names of all candidates to be voted for, together with a space for the insertion of other names if the voter desires to bestow his franchise on other than the regular nominees. Opposite each name is a blank square where the voter can indicate his choice by making a cross. Specimen ballots on colored paper are posted up outside, and cards of instruction as to the marking are provided. The voting is done inside a room provided with small shelves placed in compartments formed by wooden or canvas partitions. These compartments and the ballot-box are within a guard-rail, and at least six feet distant from it. The voter passes the guard-rail, receives his ballot, and retires alone to a compartment, where he marks his ballot, folds it so that the marks cannot be seen, deposits it and leaves the inclosure. In the case of blind or disabled persons, or of illiterates, an election officer, or, better, two of different parties may assist the voter to prepare his ballot, the ballot being so indorsed. [In the case of the latter class, in this country of free schools and unlimited educational advantages, any man unable to read and write the English language should be deprived of the right of suffrage. Placing the ballot in the hands of such persons is one of the greatest menaces to a free government. EDS.] There are numerous advantages possessed by this system over the one to which we are accustomed in this country. The ballot is absolutely secret, and no one can know how the elector voted unless he himself chooses to reveal it. This strikes at the very foundation of the power of the "machine" in politics. It makes the elector independent of any influence that might be exercised over him by any person or corporation interested in the way he may vote. It will be likely to do away with bribery, for if a voter was paid for his vote, the buyer has no means of knowing whether the contract was fulfilled except as he trusts to the word of the voter, and this he will very likely hesitate to do. It also impresses upon the voter a sense of responsibility by compelling him to make a selection of candidates for himself when it is just as easy to vote for one as another. The system also renders it easier for an independent candidate to secure an equal chance at the polls. The government pays all election expenses, so that a poor man has an equal chance with a wealthy opponent. Once nominated, a candidate cannot be "traded off" or "sold out," and any one familiar with American politics, knows how much is implied in this. The best proof of the efficiency of the system to accomplish the desired reforms is found in the fact that it has steadily been extended, not only throughout Australia and New Zealand, but also through Scotland, Ireland and Wales, Canada and Belgium, while some features of the system have been introduced in several other European countries. In this country, Louisville, Kentucky, was the first to put the system in operation, the election last December being held under its provisions, and showing a wonderful improvement in purity and freedom. Massachusetts was the first to adopt the system for the whole State, and several other States have followed her example. The governors of New York and Connecticut have each vetoed measures passed by the legislatures. Similar bills have been introduced into the legislatures of more than half the other States. The adoption of this or some similar system seems to be only a question of time. Edgar Fawcett contributes the complete novel, a romance entitled "Solarion." The fourth and last of the "Recollections of George W. Childs" is given, and deals with "the treasures" of his library. It is needless to say these are rich and rare. Some of his closing words are worthy of being remembered. "The greatest pleasure in life is doing good to others..... Being generous grows on one just as being mean does." "The Log College and early Presbyterianism in Pennsylvania," gives an interesting account of one of the earliest institutions of learning in the colonies. J. B. Lippincott Company, Philadelphia.

SCRIBNER'S MAGAZINE for September has the last of the series of 12 railway papers by H. G. Prout, editor of the Railroad Gazette. Under the heading "Safety in Railroad Travel," he describes those appliances which tend to make traveling by this method the safest of all known, unless it be by the primitive one of walking. From the statistics given of the number of passengers killed and injured in a single year, a person may reasonably calculate on riding 51,000,000 miles before being killed, or 12,000,000 miles before being injured. In other words, he might travel 30 miles an hour for 194 years before being killed. The most important appliance is the brake. Stephenson's steam driver-brake was patented in 1833, and although it never came into general use, the same principle is applied on many engines in use at the present day. The automatic air-brake is used all over the world, the Westinghouse being described as representing the most approved type. Different kinds of brakes are illustrated and described. Next to brakes in importance are signals. These have been used in great variety, but within the past few years the semaphore signal has become the general standard in the United States. The system of interlocking switches is very clearly described and illustrated. The most important signals to the general public are those which protect grade crossings, as statistics show that there are more deaths here than among passengers carried. There are several methods of guarding these dangerous places, the most common being the well-known arm-gate. Some space is devoted to heating and lighting cars, to couplers, and other devices intended for the safety both of the passenger and the employé. Some illustrations of wrecks suggest that in spite of all precautions, accidents will sometimes happen. "Night Witchery" by W. Hamilton Gibson, tells of the sights, sounds and smells of a summer's night in woodland vales, in a witchery of words that betrays the alert and enthusiastic lover of Nature. Harold Frederic begins a serial story entitled "In the Valley." It opens with one of the last raids of the French and Indians into the Mohawk Valley. The first chapters promise a very interesting story. The series of articles on fishing is concluded by an account of an excursion up the Nepigon River, in Canada, a very attractive spot for the angler. Lieutenant W. W. Kimball, U. S. N., describes "The Small Arms of European Armies," and by the aid of numerous illustrations, gives a clear idea of the murderous weapons with which the Old World soldiery are equipped for the wholesale slaughter of their enemies. Andrew Lang contributes a eulogy of Alexander Dumas. "The Fitting School in American Education" forms the subject for a discussion of the different kinds of preparatory schools. "The Master of Ballantrae" by Robert Louis Stevenson, which has been running since November, will be concluded in the October issue. Charles Scribner's Sons, New York.

OUR readers will remember that in our review of the August St. Nicholas, we left Tom, one of the Professor's party who were spending the vacation among the Florida Keys, floundering in the water making an unsuccessful attempt to stop the progress of a huge shark which they had impaled upon the grains. A month is a rather long time to leave a boy in such a predicament, but we are glad to learn in the September number that he was finally rescued, and the shark which proved to be 10½ feet long was killed. The party continued their explorations, discovering all sorts of curious things, and having all manner of adventures, in one of which Tom had a very exciting experience with a curious marine animal called a "Portuguese man-o'-war." "W. Jenks's Express" is a very touching story of a 10-year-old boy whose father failed in business, and who started in the express business with the donkey-cart he had been given for a plaything, all to "help father and mother." He did help them very materially, but in an entirely different way from what he expected. "My Deer-Hunts in the Adirondacks" is a story of a boy's adventures with a party of campers in the Adirondack region when it was more of a wilderness than now. "The Story of Turk" is a pathetic tale of a noble St. Bernard dog which lost his life in protecting and guiding monks in that mountain fastness. "Modern Harbor Defenses" are described and illustrated by Lieutenant W. R Hamilton. "The Bunny Stories" tell of Deacon Bunny's purchase of a mule, and the mishaps which happened to the younger bunnies in consequence. "Helen Keller" is the story of a blind girl and tells of her education in the Perkins Institution for the Blind, in Boston. There are other interesting short stories, letters, etc. The Century Co., New York.

INTERSTATE GRANGE PIC-NIC EXHIBITION, WILLIAMS GROVE, PA.

(RURAL SPECIAL REPORT.)

A fine site and large attendance; an assemblage of farmers, pure and simple; a fine display of implements; the principal speakers.

THE sixteenth annual Interstate Picnic Exhibition opened at Williams Grove, Pa., Monday, August 26th, and continued during the week. It was attended by tens of thousands of farmers from all parts of the country. They came in all sorts of ways—some by trains, others in stages and wagons, and hundreds walked for miles to get to the grounds. It was a farmers' pic-nic, and not a gathering of people from cities and towns to see horse-racing and the like. The grangers came, not to speculate, but to talk over matters of interest, and to see, and learn and trade. This made it one of the most satisfactory exhibitions from a business standpoint, ever held in this country. Everybody seemed to accomplish what he went to the pic-nic to accomplish, and came away tired but well pleased.

Williams Grove is a wonderful place, and the Cumberland Valley Railroad Company has done well to secure a 15-year lease of the grounds. It is a low strip of land lying between a creek and a mill-run, and covered with primeval forest trees of enormous size. It is level, but not marshy or wet, and the dense shade made it very cool even during the past week. Those who remain over-night occupy the tents, which are arranged in a semi-circle around the lower part of the grounds, and adjoining the creek and mill-run.

The implements are displayed along avenues laid out among the trees, and the visitor may wander along these avenues and not see the same thing twice. On every hand we see familiar names and faces, and implements which are used by almost every farmer in the country. On the most prominent corner appeared the name of "Jones of Binghamton." Mr. George Jones was on hand to introduce the celebrated scales of the world-renowned firm and "pay the freight." The George Ertel Company were represented by Mr. Turner, who showed the working of their hay presses. He made a number of sales. Dederick's new steel press was also shown in operation. The Geiser Manufacturing Company had a great number of traction and portable engines on the ground. One of their traction engines was tested repeatedly by running it over a log at least two feet square. A gang of plows drawn by one of their engines attracted much attention. It was paraded around the grounds led by a band and followed by a great crowd of men and boys. Messrs. Hench and Dromgold were kept busy selling their new harrow, the chief merit of which is a ratchet attachment of the tooth to the frame, an arrangement which lengthens the life of the tooth for several years. The Johnston Harvester Company made a fine display in their new headquarters. Mr. Henderson of the Richardson Manufacturing Company, was kept busy showing and selling the new Worcester Buckeye Mowing-machine. Among the dozens of well-known exhibitors I noticed the names of P. P. Mast Company; Foos Manufacturing Company; Waldron and Sprout; Keystone Manufacturing Co.; Eureka Mower Co.; S. S. Messenger Co.; Vermont Farm Machine Co.; A. Blake Co.; Lister Bros., and many others equally well known. Among the novelties were the Crane Lime-spreader, an "umbrella" tent, a combination hay-tedder and rake; a new and cheap brooder and many other labor-saving devices and implements. The "Odorless Phosphate" was shown by the patentee, Mr. Jacob Reese. It is somewhat similar to what is known in England, as "basic slag." It is a phosphate made by treating the steel ore with a lime and extracting the phosphates from the ore. This forms a combination rich in phosphoric acid (21 per cent.) and lime (45 per cent.)

The Horticultural Building was filled with fruit. Mr. Wm. M. Benninger, the nurseryman of the State Grange, was on hand and did an immense business. Large audiences attended the meetings in the mammoth auditorium. Among the distinguished speakers were the Hon. J. H. Brigham, Worthy Master of the National Grange; Prof. A. J. De Voe, the celebrated meteorologist; Hon. W. A. Armstrong, Master of the New York State Grange; General James A. Beaver, Governor of the State: Wm. M. Benninger, the distinguished horticulturist; Dr. Willets, Assistant Secretary of Agriculture; Mortimer Whitehead, Lecturer of the National Grange, and many others who spoke on subjects relating to the Grange and Agriculture.

FERTILIZERS.—Bulletin No. 5 of the Mississippi Agricultural Experiment Station is devoted to a consideration of the various manures and fertilizing materials to be found in Mississippi. As might be expected, a good deal of space is given to the proper methods of utilizing cotton seed and its products, while stable manure and the various marls found in the State are carefully discussed. Some of our best farmers will not find much that is new in the pamphlet, but it serves the purpose for which it was intended admirably.

BAKING POWDER BULLETIN.—The U. S. Department of Agriculture has been making careful investigations of the various baking powders sold in America. We receive an "Advance Slip" announcing the bulletin which is to give the results of the investigations. This seems to be the first work of the Department of Agriculture editor. Twelve powders were analyzed. A mere statement of the chemical analyses will not help us much in determining what we want. We hope the complete bulletin will give some simple facts about the chemistry of baking powders, showing why and how they act. Then readers can tell why "available carbonic acid" is used as an index of value. We are informed that there is no cause for any general alarm lest the American people should suffer injury to health from the use of baking powders. The following quotation from the bulletin concerns what the R. N.-Y. considers the most important question concerning baking powders.

"Although the investigations show that even with the best of tartrate powders the residue remaining in one loaf of bread prepared with it was of the same character as Seidlitz Powder and in quantity exceeded that of an ordinary Seidlitz Powder by over 50 per cent.; still in this, as in most cases, the character of the residue in the proportion found can hardly be regarded as generally hurtful. An exception ought to be made in regard to the class of powders containing alum to which there is more serious objection; but even in regard to that class there seems to be some difference of opinion."

After this statement we may reasonably expect that some of the baking powder people will advertise their goods as a sure cure for biliousness.

It appears that the American people pay, yearly, some $25,000,000 for baking powders. The cost of these to the manufacturers is some $8,000,000. Can we save any portion of the $17,000,000 profit? We might mix our own baking powders and save part of it perhaps. This would probably be about as satisfactory as the home-mixing of fertilizers. By the way, there is no reason why the different makers of baking powders should not be compelled to print an analysis on every can just as fertilizer manufacturers are compelled to print an analysis on every bag. One good result of these investigations will be found in the fact that many people will study the chemistry of baking powders till they understand what is needed.

WHEAT GROWERS' CONVENTION.—Last week the R. N.-Y. referred to the proposed gathering of wheat growers, and spoke of some of the objects desired by those who will attend. At the request of several friends, we now publish the call for this meeting. This call is dated at Topeka, Kan., signed by Walter N. Allen, president, and J. P. Limeburner, secretary.

"WHEREAS, That by reason of new systems in business and the combinations against us, we are not, as an agricultural class, enjoying equal privileges with the manufacturing and commercial classes, and from the inequality of exchange have for the past 10 years been sorely oppressed by the low prices of farm products; and

WHEREAS, In consequence of the depressed condition of the wheat market and the conflicting reports of the world's supply of this cereal, be it therefore

Resolved, By the charter members and stockholders of the Farmers' Federation that a convention of wheat growers of the Mississippi Valley, be and is hereby called to meet at St. Louis, on Wednesday, the 23d of October, 1889, for the purpose of discussing measures for relief, and to form a wheat growers' association.

Resolved, That the apportionment of representatives of said convention be one delegate from each county in the respective States and Territories included in the Mississippi Valley. And that the primaries to appoint delegates to said convention be held at the county seats on Tuesday, the first day of October, 1889; and that we request that the proceedings of said primaries be immediately forwarded to this office, Topeka, Kansas.

Resolved, That any farmer in the United States or Territories who has grown 500 or more bushels of wheat the past year, and shall certify the fact to the president before the meeting of the said St. Louis convention, may be admitted as a delegate to said convention. Also, all editors of the agricultural press of the United States shall be entitled to seats in said convention.

Resolved, That we advise the farmers of the Northwestern States and Territories to hold their wheat off the market until after the meeting of the St. Louis convention of wheat growers, unless such prices be offered as will justify a reasonable profit over the cost of production, or $1 per bushel for wheat. Farmers assenting to this suggestion are requested to send their names to this office with statement of bushels of wheat on hand, grade, etc.

EXPERIMENT ORCHARD.—Bulletin No. 4 of the Maryland Experiment Station. This station seems determined to make a specialty of testing and comparing varieties of fruits, vegetables and forage plants. An experiment orchard containing apple, peach, cherry, apricot, pear, plum, nectarine and quince trees was set out last December. The object in planting this experiment orchard seems in every way admirable. It is proposed to test the standard varieties that are said to do well in various parts of the State, and to compare stock from Northern and Southern nurseries. For example, trees from nurseries in New York and Maryland have been set side by side and will be closely watched during their development. Again, efforts will be made to compare the effects of various fertilizers on fruit trees. Such an experiment ought to be valuable and we hope it will be faithfully carried out.

EXPERIMENTS WITH WHEAT.—Bulletin No. 7 of the Kansas Experiment Station. This is a valuable pamphlet. Prof. Shelton is an interesting writer; whatever he has to say is practical and business-like. Wheat is an important Kansas crop—a very profitable crop when grown in connection with other crops and as a part of a regular system. It is only when it is cultivated as a specialty that it becomes a friend of mortgages and hard times. Prof Shelton recognizes this fact. He says:

"Wheat-raising upon a large scale and carried on as a specialty deserves condemnation in Kansas, as elsewhere; but when the crop is grown as a part of a system in alternation with corn, oats, grass, and other crops, it is almost certainly a profitable one to the farmer. It is one of the few crops that give returns in actual cash, and this cash comes at a season when ordinarily there is little upon the farm that is salable. The indications now are, that Kansas farmers will "go into wheat" extensively again the coming fall, and invite the disasters which have before followed the special cultivation, on a large scale, of this cereal. One of the most discouraging facts to those who are striving for real and substantial progress in agriculture is the almost constant need of attacking old fallacies in practice, which it had been thought were safely disposed of years, perhaps generations before."

Prof. Shelton's experiments are carried on with the idea in view that wheat is to be used as an associate crop, not a special one. It is often claimed that wheat affords shelter and support for chinch bugs early in the season and that these pests pass to neighboring fields of oats or corn and seriously damage them. In reply to this, Prof. Shelton states that chinch bugs have never seriously damaged his crops in good years. Will it pay to pasture wheat in the fall? If it can be done without injury to the crop, it is evident that the farmer keeping a good herd of stock could turn his wheat fields to a profitable use. Prof. Shelton's experiments seem, on the whole, to indicate a loss from pasturing, but it is quite evident that he thinks well of the practice under some conditions. A number of experiments were conducted with a view to determine the best sorts of wheat for Kansas. Prof. Shelton says that the testing of varieties is the most unsatisfactory work that comes to the experimenter. He therefore cautions his readers against considering the facts in his table of results as anything more than suggestively useful. To sum the matter up, he says:

"The wheats that are really successful in Kansas, for a series of years, so far as my observation has extended, are reds, soft or hard, and all agree in the possession of the qualities, earliness, hardiness, and compactness of habit. The early-ripening sorts are liable to escape our too-fervent suns of late June and the ravages of the first brood of chinch-bugs; while their compact habit and abundant stooling furnish the dense, moist shade, which repels the mature "bugs" by which alone these varieties are likely to be damaged."

After some experience with manures and fertilizers on wheat, Prof. S. concludes that the better class of Kansas soils, when well farmed, during favorable seasons, require little in the way of artificial stimulation. The fertilizers he applied to his experiment plots did not pay a profit. Quite an interesting experiment with salt as a fertilizer is given. During recent years salt has been discovered in great abundance in various parts of Kansas. Since these discoveries great expectations have been raised regarding the influence of salt on Kansas crops. So much has been said on the subject—mainly by those who most desired that Kansas salt should increase Kansas crops—that farmers are in danger of losing sight of the true value of salt as a manure. Last year on the college farm at Manhattan, the use of salt gave a gain at the rate of nearly five bushels of grain and 800 pounds of straw per acre. This year the salted plots gave no increase of grain and but a slight increase of straw. This experience serves to emphasize what experimenters with salt for ages have taught. It is a special manure in the sense that it must be used on certain soils and in certain seasons to give best results. It is better in a dry than in a moist season and gives better results on a dry, porous soil than on a stiff clay. Many farmers have advocated salt as a useful agent in destroying chinch bugs and other insects Prof. S. states that, with him, the salted portions of the field suffered worse from chinch bugs than the unsalted portion. But the salt *did* make a brighter, cleaner straw—that effect was undoubted.

THE FARMER.

THERE is a farmer who is Y's
Enough to take his E's,
And study nature with his I's
And think of what he C's.

He hears the chatter of the J's
As they each other T's,
And Z's that when the tree D K's
It makes a home for B's.

A pair of oxen he will U's,
With many haws and G's,
And their mistakes he will X Q's,
When plowing for his P's.

In raising crops he all X L's,
And therefore little O's,
And when he hoes his soil by spells,
He also soils his hose.

Horseman.

FRENCH COACH STALLION FRANCONI.

THE picture of this fine horse, shown at figure 235, is said by a good judge of such work, to be "the finest specimen of photo-printing" he has ever seen. We are sure our readers will agree with him that the picture is very life-like and clear—more natural and true to life than any human eye or hand could draw it. There is but one criticism that can possibly be made concerning this picture. The horse stands in such a position that his head, neck and shoulders seem heavier than they really are. Any horseman, however, can readily see that this is due to the position of the horse.

Franconi, 189, is owned by Messrs Smiths, Powell and Lamb. He is an imported horse foaled April 14, 1883. He is considered one of the finest specimens of the breed now in this country. He stands 16¼ hands high and weighs 1,400 pounds. He has the typical French Coach horse characteristics:

"Blocky, compact, with very fine head, neck, eyes, ears, with superior shoulders, short, well coupled back, excellent quarters, with well arched ribs, round full barrel, full chest, superior lung power, smooth, clean, hard limbs, the best of feet, with high, straight, firm knee action and splendid road gait."

There is no class of horses that sell so well in the New York City markets to-day as shapely and well-colored coach and carriage horses. There is always a demand for such animals, and the chances are that this demand will increase rather than diminish. It occurs to the R. N.-Y. that this is a profitable field for Eastern farmers to enter. The hilly Eastern farms from which the beef cattle have been driven by the trade in dressed-beef, cannot profitably produce heavy draft horses, and the trotter requires too much time for training. Why not coachers and carriage horses? The R. N.-Y. believes that it will be hard to find more profitable live stock for Eastern farms than grades out of good farm mares from such an animal as we have pictured. There are many reasons why French Coach horses should be selected for the production of salable grades. They are unquestionably very strongly bred and impart their prominent characteristics to their progeny. They are of fine size, usually well proportioned, with strong, cordy limbs, fine heads and necks, intelligent faces, good backs and loins and good, roomy chests, and the finest kind of action such as is desirable in a fine, showy coach horse They are also speedy enough to be desirable. They are hardy and seem to adapt themselves to any part of our country where they have been introduced, and while the best crosses are made on large coaching mares, when crossed on the common mares of the country, the get are of fine size and good action and make horses that readily sell at good paying prices both for the city carriage or coach and for the general purposes of the farmer. The grades are in demand, especially by parties supplying city trade. They are kind and gentle, require no especial training and they can be broken to drive quite as easily as Clydes. We believe the grade Coach colt will sell for more money and more readily than the grades of either Clydes or Percherons among the general public, though this might not be the case in a purely agricultural community. Breeders write us that they do not recall a single worthless colt of this breed, and they have been crossed on all kinds, styles and qualities of mares.

FRENCH COACH STALLION, FRANCONI, FROM NATURE. FIG. 235

THE SHETLAND PONY.

AWAY far beyond the north of Scotland, in the bleak, wind-swept Shetland Isles, is the home of the Shetland pony or Sheltie. It is the product of its environment, which necessarily makes it small and hardy. Of the 100 Shetland Islands, comprising about 450 square miles and scantily supporting a population of about 30,000, not more than one-fourth are inhabited. Their bold and precipitous coasts vary in hight from 500 to 1,200 feet. The rugged, rocky interior is not much higher, and is generally covered with scanty herbage or, more commonly, with a thick coating of moss, the only tolerably fertile soil being in a few valleys opening on the bays in the larger islands. A northern trend of the Gulf Stream temperers somewhat the extreme cold of the islands due to their far northern latitude, but for a large part of the year the weather is wet and wildly tempestuous and fogs are heavy and frequent. Like the usual products of an inclement climate and sparse means of subsistence, all the live stock of the group are very diminutive, and of them the Shelties are much the most important. Great numbers of these are bred on the heaths and niggardly pastures of the interior, their rough, shaggy coats and vigorous constitutions enabling them to withstand all the severities of the long, bleak, dark, cheerless winters on the scantiest fare. When the depth of snow on the uplands prevents them from picking up a meager subsistence from the withered pastures, they make their way down to the sea-shore and manage to make as good a livelihood on the kelp and sea-weed tossed upon the tempest-beaten beach. So large has been the demand for these diminutive ponies of late that much more attention than was formerly given to the matter, has been recently bestowed on breeding and rearing them; but the conditions of the climate and vegetation of their birth-place still keep them stunted and hardy. When captured and tamed, they require little feed or care. They are the smallest variety of the horse, their hight varying from 34 to 44 inches, few reaching the latter size. They are round, close-ribbed with small, well-shaped heads; ears small; eyes large, bright and intelligent; neck short and thick, set off by a long, coarse mane; shoulders long and muscular; loins broad and well formed; quarters moderately large; back gently curving; legs and feet well formed and of a splendid texture; tail long and abundant; color chiefly bay, brown or a rusty black, chestnut and grays being extremely rare.

The endurance of Shelties is great and their strength is vastly disproportioned to their size. Indeed they can easily carry a man upwards of 150 pounds in weight if he can only arrange his legs so as to keep them off the ground. They can be easily trained and are affectionate and very good-tempered. Their amiability and size well adapt them for the use of children, with whom they are prime favorites. For years large numbers have been imported into England for the use of her aristocratic little ones, and of late years considerable importations have been made into this country, where they have brought remunerative prices. The exported animal, however, nicely clipped, neatly trimmed and well fed, presents a vastly more handsome though less picturesque appearance than did, erstwhile, the same spare-boned animal with coarse, shaggy coat, long, tossing mane, and sweeping, bushy tail in its inclement northern home. Our illustration, however, reengraved from the London Live Stock Journal, represents a Sheltie in his natural condition, except that he has somewhat more flesh than his untamed brethren usually carry. See page 622.

Hygiene.

FARM SANITATION.

The earth-closet a great sanitary device; how to manage one; "terrible examples" of the evils of well-water pollution from privy and stable-yard; a modern Cassandra's predictions also disbelieved; wisdom swerves not for ridicule; a salutary warning.

I WAS frightened, yes, really, frightened to learn from the Rural's "Brevities" of February 9th, that the earth-closet had but just got its first practical test at the RURAL homestead. The difficulty with earth-closets is, that the labor required to make them do their work nicely is either forgotten or grudged on the average farm—often enough at a terrible cost. To popularize much needed reform by the general introduction of the earth closet, the latter must be made at least possible expense and labor. We have not used a vault in 25 years, depending altogether on earth during that part of the year in which earth can be had unfrozen. A door at the back of the privy admits a box on runners or wheels where the building itself must contain the earth used. We have one in use that is simplicity itself. It stands at a considerable distance from the house, behind a tree that is overrun with vines in summer and

hides it. The seat is 14 to 16 inches higher than usual from the *ground*—not from the floor of the privy—so as to make more space underneath. There is a horizontal hinged door, made to turn up at the back. Earth is thrown in as needed from the rear by means of a shovel which always stands there. Whenever needful the earth is scraped out clean with the hoe, and as it is odorless, just like clean soil, no one dreads the job at all.

It makes several loads of good top-dressing per year. During winter coal ashes and sawdust take the place of earth. I wish some one who knows would tell how gypsum (land-plaster) answers the purpose. Nice people object—and with good cause—to the dust that flies up when the earth or ashes, especially the latter, are thrown in from above. We never use wood ashes. To throw it in from the back is much the best plan. A "hopper" can be put on the back of the building and be kept full of the absorbent; the receiving box should be put on castors or home-made wooden wheels and made to pass under the hopper by turning a crank or pressing a lever, the motion of which at the same time discharges a quantity of earth or ashes into the box, reversing the motion to bring back the box. Other devices that I like much better, especially for children, are attached to the seat-cover, charged with earth from a box in the building, and dump themselves by being shut.

My attention was drawn to this subject many years ago by some English writer, and my ideas were made practical by what befell some dear friends. While calling at Hill-side Farm, I was horrified to note that several days' heavy rains had flooded the whole back yard with a coffee-colored liquid that came from the privy-vault, the hog-pens, stables and manure heap.

"For mercy's sake!" I exclaimed, "Don't use water from your well, and do drop all other work and drain your yard and move some of those outbuildings."

"Pooh!" said my friend, "so soon as the ground thaws, it will absorb this offensive liquid, and in the mean time, don't you see what nice bridges we have laid to walk upon? It would cost from $10 to $20 to do what you propose and use up ever so much of the men's time, besides."

"But this polluted water will soak into the well and give you typhoid fever," I persisted.

"I'll risk it," was the laughing answer.

But within four months typhoid—malignant typhus, the doctor said—attacked the whole family except one daughter who was away from home. My friend lost her most promising son, her mainstay, and besides losing that most precious life, the other evils that sickness brings we can imagine. She became so deeply indebted to her doctors who lived 12 miles away and charged from $20 to $30 per visit—as they do to this day—that she had to give up the dear old homestead. However, she said that a place on which eight such usually healthy persons as they were would sicken in so short a ime could not be a healthy one, and she did not regret its loss.

Only two years before, their nearest neighbor—a relative—was showing me their fine farm stock and well-filled hog-pens when I noticed that they had placed their well in a "sag," at a point where it must needs receive all the drainage from the barnyard that lay high, dry, and warm in a cozy southeast hollow on the slope of the hill. The home stood near the foot of this hill, sheltered by it from cold, northwest winds, open to sunshine—a real snuggery.

"Oh pray, pray, do dig a new well out there, or there, or there," said I pointing out various places out of the line of drainage from barnyard and privy. "You will surely be sick, now that your outbuildings are all located in that hollow above the well; so surely as water runs down hill there must be poisoning of the water in your well from those things above it."

"Nonsense!" was the answer; "this well is 75 feet deep and there is no chance for any uncleanliness to leach through that depth of soil. It's an impossibility."

When only a few weeks later, this iron-constitutioned farmer lay deadly ill, the doctor's bill alone amounted to much more than the cost of digging a new well would have been. But that was not all: in autumn of the same year their only son had just such an illness and the mother died a year later from spinal meningitis. The father, his constitution weakened from typhoid fever with which he had begun the programme, soon followed her.

The son, left alone, married and moved away, and what was once the cheeriest home in the State to visit, now stands empty and desolate, making my heart ache every time I drive past it on my way to the Post Office.

It has not been very easy for me to bear all the ridicule heaped upon me for refusing to drink or use for cooking water from an average well; but I run down the steep hill at the foot of which a jet of pure, soft water comes out of the sand-stone and carry up the water with a conscience void of offense. I imagine that I *know* of a certainty what broke up the homes and families of those friends of mine, and I will take no risks.

E. S. LINCOLN.

The Sw mcherd.

COOKING FEED.

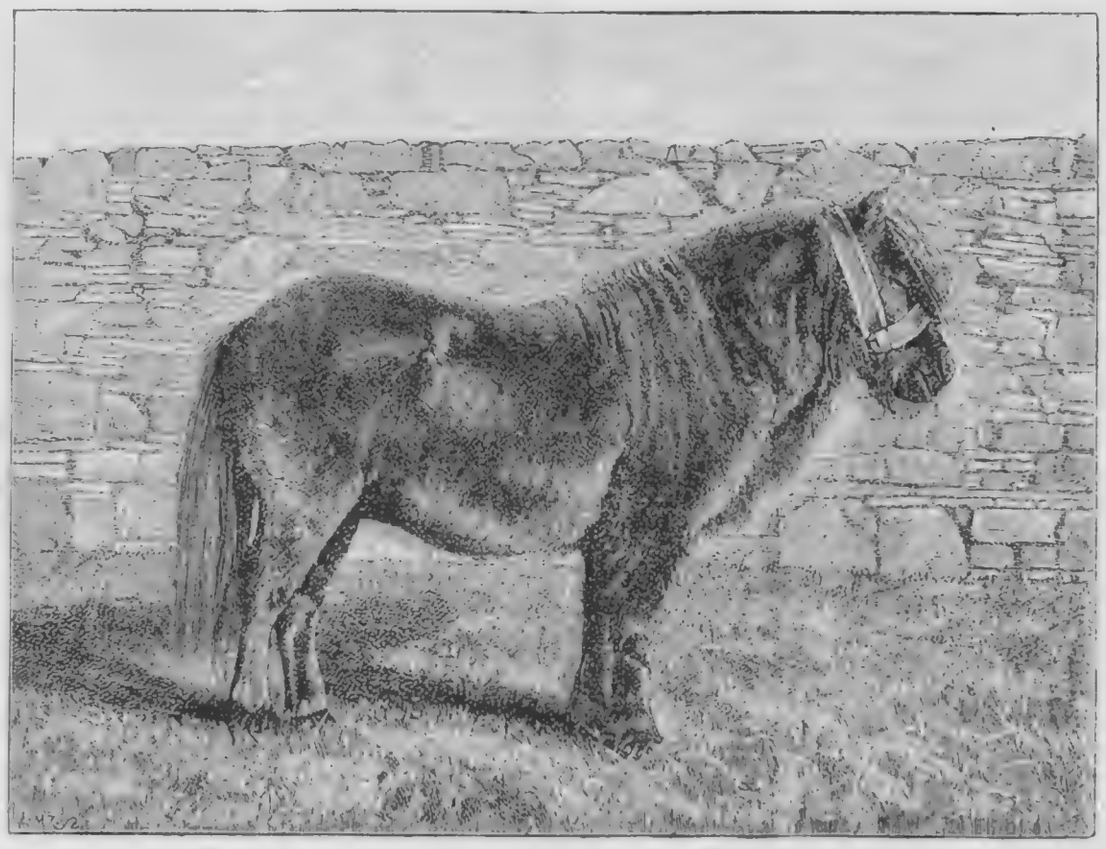
NOTES ABOUT THE PRACTICE

BY

FARMERS WHO FOLLOW IT.

IT PAYS FOR HOGS.

Some Doubt About Other Stock.



A SHETLAND PONY.

RE-ENGRAVED FROM THE LONDON LIVE-STOCK JOURNAL. SEE PAGE 621. FIG. 236.

OUR experiment stations have had considerable to say about the economy of cooking food for farm animals. Most of the experiments tried at these stations have given results unfavorable to cooking, and those who write for the farm papers generally use the figures gained by these experiments rather than the experiences of practical farmers. The R. N.-Y. has faithfully reported the conclusions of the experiment stations, all of which have stated that cooking feed will not pay. Now it proposes to give the other side. It is a fact that the business of the manufacturers of feed steamers and boilers is increasing all the time. Each year finds a greater number of farmers who cook and steam food for hogs and cattle. They are good business men, too, who understand the difference between loss and profit. It would seem that such men are well qualified to discuss the matter intelligently. The R. N.-Y. submitted the following questions to a number of these farmers. Their answers are given below:

1. Does it pay you to cook food for stock?

2. What kinds of animals do you feed?

3. What grains or fodder are most profitably cooked?

4. Have you ever made any experiments to show how well cooking pays you?

5. What is your daily practice of feeding?

6. How much stock must a farmer keep in order to have cooking pay him?

FROM ELI ROBERTS.

Cooking feed for stock does not pay for the trouble and expense except with hogs where they are confined on dry feed. I know they will do better on cooked feed once a day. My experience has been that hogs on dry feed (that is, corn and water without grass or swill of any kind) become costive and will not fatten unless they have a change of food. Here in Iowa corn is our main feed for hogs, and by feeding alternately cooked and raw feed we keep their digestive organs healthy. I have had a good deal of experience with hogs, in cooking feed. I keep from 200 to 400 head a year, but have never weighed my feed and pork when cooking feed; still I am satisfied that where hog raisers have not a variety of food, as in Iowa, it will pay to cook part of the feed. But I think where one has not so many hogs (say only 25 or 30) and can give them a variety of feed, such as mill feed or swill from the house, milk and dish-water, etc., or where the hogs get a little grass, it would not pay to cook any feed for them. A good clover field is worth more to hogs than any feed cooked in summer time. It doesn't pay to cook feed for other stock. For hogs only grain—corn, oats, barley, rye, etc.—can be profitably cooked. I have never made any scientific experiments in this matter. I cook my feed thoroughly and feed all the hogs will eat once a day. If I cook ground feed I feed it about as thick as it will run freely out of a bucket, and never feed it warmer than at a milk-warm temperature. I do not think it would pay to cook feed for less than 50 hogs. It is a good deal of trouble to fire up and cook feed every day and farmers are very apt to neglect it. I know of farmers who have bought steamers and never used them at all because doing so would cause too much trouble.

FROM W. E. PENDLETON.

I have read from time to time the long and startling array of figures against cooking food by the learned professors of agricultural colleges and directors of experiment stations, but still I keep on cooking feed, perfectly satisfied with the results without being able to bring the same amount of figures to explain the cause, partly from a lack of time and partly because, perhaps, I do not know enough. It certainly pays me to steam or cook feed from the fact that I can keep my hog stock for about one-half the outlay they would cost me did I attempt to feed them grain and roots without steaming, because my hogs will not eat roots raw and the grain costs too much to feed alone. Perhaps had I been able at first to get swill enough from private residences and hotels to feed my stock all winter, as I do in the summer season, I would never have been such an enthusiast for cooked feed as I am at present; but I could not, so I made my plans to raise roots, etc., to feed them in winter time, to save so much expense in grain; but after feeding grain and cut roots time after time, only to find the grain eaten clean up and the roots left in the trough, and hogs squealing for more feed, I set about to find a remedy, and I found it when I commenced to steam my grain and roots together. Then everything was eaten clean; the hogs were satisfied, and instead of shivering on cold days over cold feed, they got it warm and it did not take one-half the usual quantity to keep warmth in the animals, and it would, I am afraid take all the figures of all those learned professors and directors to cause me to change my mind and convince me that it does not pay me to cook my feed.

I cook it only for hogs, but still if I were keeping cattle, I would certainly connect one of the steam pipes with the water tank; but I hardly think I would attempt to steam food for cattle. My opinion, however, is in favor of hog stock as the most profitable stock to cook feed for. For the hogs one should cook every thing from early in the fall till late in the spring, then get them out-of-doors into the grass pasture, if one has such; if not, he should have yards out-of-doors, and feed sparingly of grain, but give plenty of soiling crops. Clover I think is the best, and peas are next. As for myself, I depend partly on grass feed and partly on fresh swill obtained mostly from summer residences every day.

In one sense I have made no experiments to determine how much the cooking pays, and yet in what is to me the main point I have. I do not have time to weigh the hogs; neither have I convenient means of weighing them to determine by long columns of figures the *pros* and *cons* of the matter; but, nevertheless, the hogs thrive, grow fat, are perfectly healthy and breed better. And, again, I say it does not cost me one-half so much to feed them when I use cooked feed, as it would if I fed a grain ration alone, nearly the whole of which I should have to buy.

My system of cooking I can easily explain: I have, first, a Purington steam generator burning either wood or coal. The first thing every morning the hog-man opens up the draft and gets a good fire going. After feeding all the hogs and pigs, he prepares a barrel of food holding about 50 gallons, turns on the steam and in from half an hour to an hour the feed is cooked, the time depending, of course, on the briskness of the fire. While the feed is being cooked the hog-man is preparing another barrel, cleaning out the pens, bedding down, etc. This work is repeated from three to five times every day, according to the number of hogs and pigs we have in hand. My ration now—and it has been the same since last fall—is steamed cabbage. We fill a barrel about one-third full of chopped cabbage, then put in a layer of grain—sometimes middlings, but mostly flour—and alternate layers are put in until the barrel is as full as it can be packed. We use from one to two bushels of grain to each barrel, the amount depending on whether the feed is for sows with pigs, shoats that I am fattening, or sows that are in farrow. The last are fed more lightly to prevent them from getting too fat. The cabbage will shrink about one-third when mixed and steamed in this way. The flour is bought from a cracker factory, and consists of fine flour sweepings which cost one dollar per barrel, and are the best feed for growing pigs I ever used. The cabbages would not have paid freight, cartage, and commission last fall and winter.

The hogs did not eat them well raw, but when steamed with a little grain they ate them and did wonderfully well on them. They paid me well for feed alone. Later on in the coming winter, I shall feed parsnips, turnips and small potatoes, mixed with grain and cut up fine. Pea-straw, hay and cured clover I fed twice each day. This I find sufficient with my line of stock, which consists of Yorkshire hogs. As to how much stock must be kept to make it pay to cook feed for them, in the Eastern States, where grain is expensive, it would pay all the way from the person who keeps one hog for his own pork barrel to the large pork producer or the large breeder of breeding stock, only, of course, each must regulate his apparatus for cooking according to the amount of stock kept. As to the needs of farmers of the great grain-producing States, I know nothing; but in this section, the piggery must be run in the least expensive way, and with some cooking apparatus the farmer who cooks his hog feed can use a great many unsalable vegetables and other things that would be otherwise wasted.

New London County, Conn.

FROM JOHN E. DAVIS & SON.

1. It pays us to cook feed for hogs which are the only stock we have cooked for. We find ground feed more profitable to cook than unground. The feed that gives as good results as any other, if not the best, is corn ground up cob and all, and thoroughly cooked. This well salted and with enough water added to make a slop, makes a feed on which any hog will get thrifty and improve.

The only experiment we have made is one in cooking. The feed swells and makes a larger quantity, and for fattening and feeding purposes this feed seems superior to any kind of dry feed we have ever fed.

We use a Purington Steamer, cook thoroughly two barrels of meal, containing about four bushels each, at a time. This is fed while warm, as warm feed is eaten with a much greater relish during the cold days of winter, than cold.

A good full feed twice a day keeps shoats in a good thriving condition; but fattening hogs should be fed oftener and get some dry feed to make their flesh more solid.

Ten or 12 brood sows or 30 or 40 shoats will pay for all the labor and expense of cooking feed, and we think that a given quantity of cooked feed will give better results than twice the amount fed dry. Cooked feed keeps brood sows in the thriftiest condition, loose and healthy.

After feeding cooked feed one month to our sows and shoats—in all numbering about 90—we considered they were enough better, than when fed on dry feed for the same time, to pay for the grinder and steamer, and the practice is paying us now as well as it did the first month.

Ames, Iowa.

FROM PAUL LANDMANN.

Cooked feed paid me well in the case of young hogs. I have never seen pigs grow faster than mine did on cooked pumpkins, potatoes mixed with bran, shorts or ground feed of any description. I honestly would not use any dry feed for my young stock during our long winters, nor would I use cold water. Cooked oats with potatoes or any roots make all my pigs feel happy in winter time. I do not use any warm food during the summer; but as soon as the ground is frozen I begin with warm slops. I save at least half of the feed in this way. I cook two barrels of mixed food in the morning and feed one in the morning and one in the evening as slop. The latter, if covered, will keep warm until evening. I have 15 brood sows and 20 shoats. My brood sows do very well. I have no complaint to make with regard to their losing their litters as they would do if fed on raw feed when corn only is fed to them during the winter.

Tyndall, Dakota.

FROM N. A. TOWNSEND.

I have not had as long an experience as some in feeding cooked feed, yet I believe there is no one branch of farming that pays so large a per cent. of profit as the steaming of food for growing animals. Since commenced steaming food for hogs—about four years ago—I find I can make them as heavy when they are from seven to nine months old, as I formerly did when they were from 12 to 15 months old, thereby making a saving of from 30 to 40 per cent. of the time of feeding, and lessening their liability to disease by the length of time saved in getting them to market, which is no small item here in the West where cholera, swine plague, worms and other diseases take our hogs off by the score.

I have never had any practical experience in cooking feed except for hogs; but my opinion is that it will pay as well for milch cows and calves as it will for hogs. I have never had any experience in cooking fodder except steaming a barrel of clover or Timothy as a relish or appetizer, which I believe answers the purpose of preventing disease better than anything in the way of medicines or cholera cures that I have ever tried, and I believe the feeding value of any kind of grain is largely increased by cooking, and certain kinds of vegetables that are almost worthless as food for hogs in their raw state, become excellent food when cooked, and make a decidedly healthier food than all one kind of feed fed raw.

I have never made any careful experiments to show the profits from cooking hog feed, but at one time I kept an account with my pigs to see whether it was profitable to raise them or not, and the results were very satisfactory. I had 44 pigs farrowed in May and June, which I sold on the first of November, that averaged 204 pounds each and which were raised at a cost of a fraction over 1¼ cent per pound. I bought my feed at the mill all ground; fed some bran and shorts, and also corn and oats ground together. I made a thin slop of some, and a thick mush of the rest. I did not charge the pigs with the slop from the house or the pasture, as other stock were running in the same pasture. I think this a very good showing, for if we can, by cooking or any other method, reduce the cost of raising any animal until it will make a good profit on the investment, it is just what we are all striving for—to get the largest amount of gain with the least possible cost.

The reason why farmers do not feed more cooked feed than they do is because of the time taken to cook it in the old way—with kettles—and the liability of burning thereby nearly destroying its value. Unless one stays with it and stirs it constantly, it is very liable to burn, and the cost of the time it takes to cook the feed in this way overbalances the increased value of the food cooked; but by cooking with a proper steamer, this is all obviated, as it does its own stirring and one can cook as much or as little as he pleases with no danger of burning.

I cook from one to three barrels at a time, the quantity depending on the amount of stock to be fed and the time of the year. I feed it slightly warm (not hot) three times a day. So far as my experience and observation go, it will pay to cook feed where there are three or four cows and 10 to 15 hogs, as a person can cook their feed and still do his usual share of work in the field. I know quite a number of farmers in this county who have been cooking their feed (or a portion of it), for the past two years, who claim that they save at least one-third of the feed besides having healthier stock and getting them to market heavier than when they fed all their feed in a raw state. It seems to me that the only question to be decided is what portion of the food needs cooking, for all with whom I have ever talked on this subject, claim that it pays to cook certain portions of their feed in order to secure a healthful change and also to get the best results.

Dallas Center, Iowa.

FROM J. F. COULTAS.

I have not used cooked feed for fattening purposes. I sell most of my hogs for breeding purposes, and have not had anything but culls to feed off. I use the steamer for cooking feed for brood sows. I use good bright clover hay cut with a feed-cutter, with either bran, shorts, corn-meal or ground rye and oats. I steam the hay and meal together, and find it a fine way to keep brood sows in a healthy condition through the winter.

Winchester, Ill.

FROM E. M. JENKINS.

I have been handling hogs for 15 years, and my experience has always been that for young hogs especially, it pays to feed cooked feed. I have not tested the matter by weighing the pigs and feed, but I think any intelligent breeder can see the difference very quickly. I begin to cook in the fall as soon as cold weather comes on, and continue to do so until the advent of warm weather and grass. And I always feed the stuff while it is warm. I think that the best feed consists of corn, oats and rye ground equal parts, mixed with bran, half and half. But for fattening purposes I simply cook the shelled corn, using the cobs for fuel, and once a week I give a feed of cooked bran with some oil-cake—say four quarts of dry cake to a barrel of cooked feed, and I always salt all feed. In my judgment, no matter how little or how much stock a man may have, it always pays well to fix up for feeding judiciously and for cooking feed, thus saving everything and avoiding all waste. Very little feed will be needed to keep up animal heat, as the feed, being warm, does that. One should feed three times a day and always give warm drinking water or at least take the chill off it.

Alexandria, Nebraska.

FROM S. B. PIKE.

It pays to cook feed. I do so for hogs, calves, and milch cows. I cook corn, oats, rye, barley, corn fodder, potatoes, and, in fact, all kinds of grains or roots. I find I can put on as much flesh with one bushel—32 quarts—of cooked corn as I can with 50 quarts of raw corn. I also tested cooking for a single cow, and having cooked four pounds of corn and oats ground together per day, got an increase of 16 per cent. in the milk, and of 19 per cent. in the cream or butter. The cow was fed and watered the same as usual in every way except that the grain was cooked. I also tested it on my driving horse, and found that he could do the same work on eight pounds of cooked corn and oats that he did on 12 pounds of raw, and he looked and felt better. I fed him the same number of pounds of hay in each case. For cooking I use a small feed steamer when I have to feed five hogs and upwards; and for a smaller number I cook sometimes on the stove, and sometimes with the steamer. I cook every day in summer as well as in winter, if I am feeding not less than one bushel per day, and if I am feeding less than that I cook every other day.

I can make it pay me to cook for one single cow or hog. In such a case I would cook on the kitchen stove; but I would run the steamer at a profit in cooking feed for five cows, or five hogs or four horses.

I claim that it pays me from 20 to 40 per cent. to cook roots, the profit depending on the kinds of stock I am feeding. One bushel of steamed potatoes I value more highly than I do one bushel of raw corn for young pigs or calves. I used not to have time to cook; but according to my experience during the last four years, if I have not the time, it would pay me to hire some one to do it for me for a lot of 20 or 25 hogs. I want my stock fed just at the same times each day. I usually feed night and morning as regularly as it can be done. One of my neighbors put 52 pounds of flesh and fat on a 250-pounds hog in 30 days on cooked corn, and 30 pounds on one fed on raw corn. In all my experience I have not known a single farmer who makes a success of his business who does not own that it pays him to cook grain for his hogs if he has once tried it. In cooking with my steamer all that is needed is to put in four or five pails of water and build the fire, and put the feed into the barrel or tank. I usually do it after feeding in the evening, and it is all ready to feed in the morning, and it pays me from 20 to 33 per cent. to do it.

Ingham County, Mich.

A MARIN COUNTY, CALIFORNIA, DAIRY. SEE PAGE 624. FIG. 237.

THE INTELLIGENCE OF THE HOG.

PORK RAISING IN THE SOUTH.

HENRY STEWART.

Great intelligence of hogs; fine opportunities for hogs in the South; superiority of their meat; folly of buying Western pork instead of raising enough at home; life of a Southern hog; a profitable experience in hog raising; a sensitive conscience; "pinters" given by the Northern "schoolmaster abroad" in the South.

THE man who thinks a hog is without intelligence makes a great mistake. Mr. Berghaus has given the readers of the RURAL a good lesson in this respect. There is an air of thoughtfulness about his drawings, in a late RURAL, which at once attracts the experienced pig breeder and feeder, and he truly represents a typical animal of this ill-used and misrepresented race. In its exhibitions of instinct and intelligent actual reasoning the hog comes next to the horse, and for cuteness quite surpasses even that noble animal. The trouble with pigs most commonly is that their owners are themselves deficient in intelligence and do not give their pigs a chance. All the difficulties in rearing pigs and bringing them to market seem to me to be incident to the restraints put upon them by their owners. For instance, when running at large on a range a sow never kills her young pigs, and always provides her brood with a warm, dry, safe and healthful nest. I should have liked to have contributed some "pork points" to those interesting experiences given by several contributors in the RURAL of August 7, in regard to the management of these animals in the South where the hog has a good deal of freedom and evinces intelligence of no mean order. But here, too, the hog has not a fair chance and is subjected to many drawbacks, in consequence of which he comes to undeserved grief and reproach. It is well known that the South buys most of its pork from the West where the hogs are spoiled by too much corn feeding and run to unhealthful and unwholesome fat—unhealthful for the pig and unwholesome and unprofitable for those who consume the meat, or rather grease. The common Southern hog is usually of the razor-back or slab-side variety. But the meat of these pigs is far better than that of the rotund, barrel-shaped Western hogs, without any head or neck to speak of and not enough muscle on their frames to carry around their load of fat. Southern farmers are now paying 12 to 15 cents per pound for Western bacon, while the very best of pork can be produced for two or three cents per pound, or even less, in such favorable localities as the mountain region, in an average of years. The pigs here live in the woods winter as well as summer. They choose an open place for their nests in some sheltered place, where they gather leaves and brush into a broad heap elevated a foot or more above the ground, and therefore dry and warm. They do not go into hollow trees or caves where a man would put them, if he could, for shelter; and in this they show more intelligence than their owners, for this sort of nest would soon become filthy or muddy, and would not dry as the leaf-bed does after the heavy rains. In these nests a sow will rear from eight to 13 pigs successfully. Let me give a little of my experience gained in pursuit of useful knowledge and in some tests in the direction of the actual cost of making pork in the South.

A sow and seven pigs were bought in the early spring for seven dollars, and were turned into a wood lot. They were given the waste milk and butter-milk for which there was no other use. The young pigs were given three bushels of corn, in default of sufficient mast to fatten them, and when slaughtered, made very nearly 800 pounds of pork, which was cured into bacon, and sold for 10 to 12 cents per pound; it could have been sold for 15 cents, but my conscience forbade the exaction of the full market price. The meat was of the class known as breakfast bacon, such

as is sold wrapped in paper and canvas at an actual price, to the customers, of about 25 cents a pound, wrappers included. The returns from these seven pigs made nearly $90, and the sow was left. She had eight pigs the next fall, and when these were weaned, she was turned into pork, and made $20, at a cost of less than $2 for corn for finishing. The chestnuts and acorns in the woods made nearly all the meat without any cost at all, and the corn was really unnecessary. The pork was quite half lean, very tender and sweet, but lank and thin, the hams being broad. and not more than four inches thick in the most fleshy part. This meat is of precisely the same kind as is sold in Europe at a high price as Westphalia hams and bacon, which is esteemed a delicacy for the flavor and sweetness contributed by the nuts and roots upon which these forest-fed pigs live. I have now the young pigs and a sow which I bought for $2 last winter, and as the mast will be abundant this season, they will get fat enough to eat without a grain of corn. They are now getting the waste milk of two cows and the small and half-rotten potatoes fed for experiments as to their safety. They will make considerably over 1,000 pounds of pork. If one will figure up the cost of all this pork, I think he will estimate that it is not quite two cents per pound, including some charge made for the waste milk and the man's time in carrying it to them, which is about 10 minutes daily.

Now there is no reason why nearly every Southern farmer could not do this. He has plenty of wood-land for a range; he has some waste milk or may have; he can grow peas and sweet potatoes; he has old fields with grass and weeds which the pigs will eat, and his sows are prolific and intelligent enough to save all their pigs, never eating or crushing them, and defending them with the ferocity of a tiger from all enemies. He has plenty of corn-meal screenings, and if he will not suffer the pigs to starve on pine roots when the mast is not in season, or when it is scarce, by having some food grown for them, he can grow all his pork and have some to sell without being able to put his finger on one single hard dollar he has laid out for it, instead of getting this provision from the stores at 12 or 15 cents a pound on credit, at two per cent. a month and paid in cotton or corn at 25 per cent. less than the market rates. These "pinters" might be useful to many Southern readers who might do as I have done; viz, talk to their neighbors about it and show them how they can save money by growing their own pork at a trifling cost, and utilizing neglected opportunities, not to speak of the advantage of affording some means for their pigs to exhibit the natural intelligence which they certainly possess. The Southern farmer is perhaps slow and a good deal behind his Northern and Western brethren in aptness and knowledge, but he can see a hard dollar when it is shown to him, although it may not be in the form of a light-weight silver coin.

Macon County, N. C.

Dairy Husbandry.

DAIRY NOTES FROM A DAIRY RANCH.

NO. III.

THE HERD, AND OUR WAY OF IMPROVING IT.

Starting and improving a dairy herd in Colorado; profitable sale of culls; milk and butter dairying; profits from a pure-bred bull; how and why Holsteins replaced Jerseys; advantages of thoroughbreds over scrubs; praise for Holsteins; care of a dairy herd.

TEN years ago it was a difficult matter to pick up 50 fairly well-broken milch cows in Colorado. Cattle running on the range then represented largely the cattle interest of the State, consequently milk and especially butter were at a premium. On the river bottoms were to be found now and then dairy ranches; also in the mountains. I bought out a dairyman and found myself in possession of 30 cows of no particular breed, whose recommendation was that with good care they would each give some milk five or six months of the year. With these to start out with, I commenced dairying. Whenever a cow that promised well could be found, I added her to my herd and sold all the butter I could make at 45 and 50 cents per pound three-fourths of the year, the price never falling below 23 cents. Having plenty of milk for the calves, I raised them all "by hand" and during the summer let the yearlings "rustle" for themselves on the public feeding ground after the manner of the Western cattleman.

For three years I managed in this way. At the end of that time I bought a ranch on the river and moved near town to take up the business of selling milk. To buy this ranch, I had to include in the purchase a small herd of very fair Jerseys, eight or 10 in all. Cattle sold readily then and my young range stock found a purchaser at $15 per head. I had 90 of these and half a dozen or so fat cows for the butcher at $30 each. The Jersey bull and several of the cows that came with the farm were registered in the Worcester herd book. Now that I was selling half of my milk I could raise only the choicest heifer calves. It was no uncommon thing for a man to kill the calf of a common cow, if he wanted the milk needed to feed it, provided he could not give the little thing away. But here I reaped the benefit of a blooded bull. The calves sired by him sold readily when less than a week old for $2 to $5 apiece, the heifers bringing the latter price. These were the grade calves from the "scrub" cows. Prices of beef cattle began to fall and it no longer paid to raise Jersey steers, they were not beefy enough. I decided to try the larger breed of Holsteins, and have something that would be worth raising for beef if it could be turned to no other profitable account.

I sold seven Jersey cows and heifers for $100 each, keeping the grades in my herd, which was already much improved by my method of culling and selecting. If a cow did not return appreciative thanks at the milk-pail for the care and food she had received, she was straightway fattened; so my 100 milch cows were much above the average. The Jersey bull showed a decided determination to fight, so he was last seen as dressed beef entering a bologna sausage establishment. The returns on him were very light.

I then bought two bulls and two heifers of the Holstein breed (yearlings) for $1,000. The calves of my common cows now sold readily as soon as dropped for $5 to $15. I still raised a few of the best, but this way of improving was too slow, and a car-load of high-grade two-year-old heifers, was shipped to me from Elgin, Illinois, at a cost not exceeding $40 per head. The first calf from this purchase was a bull and brought at six months old, $80; the other bulls sold for prices varying from $25 to $75 according to the markings of the creatures. I raised all of the heifers myself; the sweet skimmed milk from the Cooley Creamers making this an easy thing to do.

As my heifers came in I had cows to sell. and although beef creatures were low, good milch cows sold at from $50 to $75 each. As my old cows became fresh, I found purchasers for them and gradually found myself in possession of a Holstein herd; for among the changes, 20 thoroughbred, imported Holstein cows had been added to my stock. Now prices on dairy cattle began to decline, and I sold my registered bulls for the same price I had received two years before for high grades—$70 and $80 per head.

The grade heifers I had raised and expected to receive $75 per head for, sold by the car-load at $50 each. There was no loss about that; it had cost not one cent more to raise those heifers than it would have cost to have raised scrubs that would not have brought over $15 per head, with a chance that a purchaser could not be found at any price.

Now I had thoroughbred heifers to take all the milk I could spare and the high-grade calves were sold at the prices half-breeds brought at first. In the general dullness of the times, milk and butter commanded a slow market, in my immediate neighborhood. As my supply of milk for butter-making depended upon the whims of the milk trade, I could not agree to supply a certain amount of butter without risking to be over-burdened with dairy products, so I sold half of my imported cows. These cows had proved very excellent; each cow left in my possession a valuable calf to fill her place in a year or two Despite the falling off in prices, the cows sold for all they cost me. The bulls have more than paid their first cost by service outside of my herd.

It is hoped that this paper has shown that no man can afford to keep a herd of "scrubs" without constantly improving them. If an accurate debit and credit account had been kept, no doubt the increase of the Holsteins in the four years I have owned them would much more than pay the first cost of every cow bought. Nothing has been said of their superiority as milk and butter producers. One would hardly believe what might be said of them unless he had at some time been intimately acquainted with a fine herd. Given a good cow, it is the feed that makes the extra cow. Not only is plenty of good feed needed, but regularity in feeding, too. The time is coming when the stockman will not allow his young creatures to be stunted in their growth; when he will *crowd* them with good feed, the heifers especially, so that when they are cows they can bear heavier feeding than they otherwise could. C. H.

Greeley, Colorado.

IN A MARIN DAIRY.

MARIN COUNTY, California, is a very famous dairy region. The county lies north of San Francisco Bay, fronting the Pacific. It is beautifully diversified—consisting of valleys, ridges, canons, hills, forests, streams and some very wild country. Most of it is owned by the dairymen. The Redwood forests stretch well into the county, and the remains of old logging camps are found in many places. The hill-sides and glens are full of wild flowers and such fine shrubs as the California lilacs and azaleas. In the illustration, Fig. 237, page 623, the cattle sheds have been built partly around a tan-bark evergreen oak. In the background are a few Redwoods. The milk-maid, the cattle and the whole scene are very characteristic of California dairy life. In the course of a day's travel through the Swiss dairies of the coast one will see a dozen or more milking yards in just such situations, and early in the morning the milk-maids at their work. C. H. S.

Field Crops.

REPORTS ON RURAL NO.2 POTATO.

SENEY, Plymouth County, Iowa.—I dug my R.N.-Y. No.2's on September 6. I planted one small potato cut into four pieces, two in a hill. I put on about a double handful of fine bone and phosphate. It was quite late with me. I have 20 tubers, all of good size. They weigh 7½ pounds.

J. P. V.

FAIR GROVE, Greene County, Missouri.—I cut my small Rural No.2 Potato in two pieces and planted them on April 8, according to the trench system. Each piece yielded 14 potatoes—28 in all, 24 of which were merchantable; total weight eight pounds. The largest two weighed 11¼ ounces each; the remainder were uniform in size. They were dug on August 9. I am well pleased with the result and will give the variety another trial next year. T. S.

LITTLE FALLS, Passaic County, New Jersey.—I planted the R. N.-Y. Potato No. 2 on April 10, cut into five pieces; only two came up, the others rotting. I dug them on September 9, and got seven potatoes weighing three pounds and two ounces, the largest weighing a little over 14 ounces, and the smallest three ounces. They are of good shape and smooth. G. N. E.

NATURAL BRIDGE, Jefferson County, N. Y.—I planted the Rural No. 2 Potato on May 10, and dug my crop on September 4, after the vines had been dead two weeks or more, with the following results: 27 potatoes; weight eight pounds six ounces; 18 marketable tubers weighing seven pounds seven ounces. The largest tuber weighed 12 ounces, the largest two one pound six ounces. In planting I followed the RURAL'S trench method. I cut my sample into four pieces, with two eyes to a piece, with the exception of one piece which had but one eye. I planted the pieces about two feet apart. F. E. A.

OUAQUAGA, Broome County, N. Y.—No. 2 Potato sent me was a rather inferior sample, but was cut into five pieces and planted in as many hills. They all started vigorously and were hoed once when the frost cut them down. One hill never came up again. The vines began to die from blight on August 1, and I dug them on August 19. There were 23 sound tubers which weighed seven pounds. Of these five were small, but none was as small as the sample seed. Three good-sized potatoes were rotten, making the yield 26 tubers in all. The effect of the freeze reduced the size of the tubers materially. I am well pleased with them and will be able to plant a nice plot next season. M. J. W.

CORNWALL, Orange County, New York.—The R. N.-Y. No. 2 Potato was planted about May 1. I cut it into six pieces with one eye each. These I planted in the garden in a trench 12 inches apart and four inches deep. One piece had a sprout about 2½ inches long. This I planted so as to bring the top of the sprout nearly to the surface of the ground. It came up and was nearly two inches high before the others appeared. This was the strongest plant of the six the whole season. On September 9th, I dug the tubers; there were 33 in all, which weighed eight pounds nine ounces. The hill in which the sprout was planted turned out eight nice tubers which weighed three pounds seven ounces; the largest weighed 12½ ounces; one weighed 12 ounces and one 11½ ounces. They are a very fine lot of potatoes. Those who have seen them pronounce them first-rate. C. S.

PHELPS, Ontario County, N. Y.—The Rural New-Yorker No. 2 Potato, sent me last spring, was cut into four pieces with one eye each, and planted in the garden, where potatoes had been grown for years. The yield was nine pounds. There were in all 35 tubers—27 large and 8 small, the largest weighing 11 ounces. J. L.

ZANESVILLE, Muskingum County, Ohio.—I planted the R. N.-Y No. 2 Potato about April 15. It was the size of a hen's egg and had 10 eyes. I cut it into pieces of one eye each; all grew but one. I dug them on September 6, and the yield was remarkable. There were 28½ pounds, all good-sized tubers. The largest weighed one pound and seven ounces. There were seven that weighed over one pound each.. E. W.

BAYARD, Columbiana County, Ohio.—My R. N.-Y. No. 2 Potatoes died off before they had properly matured. From the one small tuber I got 18 marketable potatoes. I planted four acres of potatoes last spring. We had so much wet weather that I find a good many rotten. I have not dug yet, but on examination I find the Early and Late Rose the most affected. I think the rot will not affect what are sound. The Potentate is the least affected. The blight affected the Burbank; there may be half a crop, but I am not able to state positively.

I. S. T.

MANCHESTER, York County, Pa.—My small Rural No. 2 Potato I planted on May 2. It was cut into four pieces, and planted in a frame made of boards with sides about eight inches high, the box being 32x34 inches. The ground was deeply worked and enriched with hen manure and ashes, and occasionally a liberal sprinkling of tobacco dust was applied to kill the wire-worm. The crop was dug August 14; result, 11 pounds 10 ounces, all of large size except six small ones. The largest one weighs to-day—10 days after it was dug—18½ ounces; another weighs 17½ ounces and two others 16 ounces each. The rest are all large, smooth tubers. I think the result is very satisfactory. The frame or box was filled up with soil from time to time as the stems increased in size, so that the potatoes when dug were about six inches under the ground—a little in the order of the R. N.-Y.'s trench system.

CORRESPONDENTS' VIEWS.

TOWN INSURANCE.—Since the formation of a farmers' club in our town (Jan. 19, 1889) the subject of insurance has been strongly agitated, and as a result a mutual farmers' insurance company was organized on Feb. 22, to which property to the amount of over $225,000 has been offered for insurance. The by-laws prohibit taking risks within corporation limits of villages, or on property anywhere within 60 feet of other buildings unless all are covered by one policy. The policy costs $2 for any amount under $7,000 which is the highest amount that is allowed to be covered by one policy. There are no other charges unless a loss is incurred. Then each policy-holder is assessed a sufficient per cent. on the face of his policy to cover the loss. The term of insurance is five years. Insurance in these companies is the safest and by far the cheapest that can be obtained—safe because the capital stock is in sight and held by men known by all insured as every man insured becomes a stockholder and is liable for the face of his policy as soon as he is insured in this company: cheaper, for fires in the country are rare, and seldom large, for generally quite a distance separates the house and barns, or should, at least, for health as well as safety. Several towns around us have town insurance companies and in one instance where a company had been in operation 11 years the cost had been only one-tenth of one per cent. per

year, or less than one-third the amount of premium demanded by old-line insurance companies.

That cartoon in the RURAL of February 2nd, showed forcibly what constitutes the farmers' load, and the profits of insurance companies and middlemen are two heavy weights we are trying to shake off. We shall be successful in a measure and have bright hopes for the future. M. T. W.

Sandy Hill, N. Y.

THE TELL-TALE ACCOUNT.—One day when I was a boy, I chanced upon what seemed to me a very old account book. The hand that had written it had long since ceased from labor; but the man whose name stood at the head of the account I recognized as a miserable churl in the poor house. Tradition connected his name with a certain broad farm. It was called the Bounds' Place.

J BOUNDS.	DR.
July 5, 1805 To 2 Quarts Rum	.30
" 6, " To 1 Quart Rum	.15
" 8, " To 6 Drinks Rum	.20
" 9, " To 1 Quart Rum and 9 Drinks	.35

Thus the account went on from page to page like an accusing angel. At the moment of my discovery Jerusalem Bounds was in the poor-house, whither his able-bodied wife had followed, and their children had been bound out by the select-men and the old home was in the hands of strangers. Farmers who are at present engaged in pouring their farms down their craving throats are hereby reminded that such accounts as the above had better not be kept for their posterity.

O. H.

EARLY PLANTING OF CORN.—The year 1889 has been very peculiar throughout. Last winter was exceedingly mild—there was not an inch of snow all put together, while ice was never an inch thick the whole winter. March was dry; as a natural consequence farmers took advantage of it to plant corn, but not to the extent that they might and ought to have done. It is the only really good corn that we have in this section this year. It has long been a well-established fact (in this section) that March corn is our safest crop, coming in, as it does, ahead of the drought that we ordinarily have in July and August. It is planted so early that the bud-worms do not interfere with it. This is the only sure way with which I am acquainted to circumvent the little pests: either plant very early—say March for this section—or very late—say June 15th to 20th. In either case the crop will be safe from the bud-worm; cut-worms do no material damage to corn, as, though they may cut it off even with the ground, this neither kills it nor checks its growth. If it is impossible to plant corn either very early or very late, all that can be done is to plant enough for one's self and the bud-worms too. Strew it about the same as you would sorghum seed. I would much rather plant an extra half-bushel, or even a bushel of seed corn to the acre than to replant, as the replants rarely make anything, and it is impossible to cultivate corn well—as it should be cultivated—when it is of all sizes. Early corn has in the cotton belt the still further advantage that it can be laid by early, and is off one's hands before the busy part of the cotton season sets in. I have heard it said, and fully believe it myself, that the oftener corn is bitten down by frost the better will the final yield be. Our March corn this year will make 40 or 50 bushels per acre; April corn about half as much; May corn nothing. We have land lying idle that was well broken and harrowed with the intention of planting it in corn in June. It rained the whole month through, so we were deterred by flood after flood from either planting corn in June or working that which had been planted in May. Exactly the same misfortune befell us three years ago. Moral: Plant early; there is nothing to be lost by it, and there is a great deal to be gained. G. H. T.

Denmark, Miss.

Everywhere.

CLIMATE OF THE PUGET SOUND COUNTRY.

AS SOON as I can collect the data I propose to write up for the readers of the RURAL something of the horticulture and pomology of the Northwest; as climate is always one of the chief factors in the cultivation of the garden and orchard, I will speak of the climate at first. But as the topography of a country is one of the chief factors in controlling the climate, I will take this up before speaking of the great influences of the Japan Current, over the climate of the coast. Puget Sound is an arm of the ocean made up of narrow bays and inlets, and owes its existence to the glacial period wherein conditions somewhat similar to those now prevailing in Alaska, existed here, but perhaps upon a larger scale. The valley is about 100 miles wide between the Olympia Mountains, which are about 8,000 feet high, upon the west, and the Cascade Range upon the east, culminating at Mt. Rainier or Tacoma, 60 miles distant, a little south of east, in a peak, 14,444 feet high, the grand central point of glaciation, from which glaciers once crawled out into the ocean, plowing out the bays and inlets as they moved onward through the Straits of Juan de Fuca. The water of a great ocean like the Pacific is always a conservator of heat from the great center of heat, the sun. The heated waters of the tropics form rivers and cause currents that flow first northerly, then bend easterly as they impinge against the currents of cold water flowing southward from the north polar circle. This current in the Pacific is known as the Japan Current. As it expands and spreads out over the area of the north Pacific, it heats the air that comes in contact with it, and causes what is known as the warm or chinook wind, that constantly blows landward from the ocean. The influences of this warm and moist current of air are felt all over Washington, Idaho, Montana and Dakota, being gradually, as it passes eastward, overcome by continental currents or winds. The influences of the chinook are felt as a silent benediction and almost unobserved beneficence without the noise or tumult of ordinary winds.

The breaks in the continuity of the Olympia Mountains, usually snow-clad at all seasons of the year, caused by the mouth of the Columbia River upon the south, and the entrance of the Straits of Juan de Fuca upon the north, must always be taken into consideration in order to understand the climatic conditions of the Puget Sound country, for they exert a more or less profound influence upon local conditions. This will be understood when we consider that the air resting upon the surface of the land or water always assumes a more or less stratified condition, especially at night, while the day is often consumed in an effort to break up these strata of air. Cold air is heavier than warm air. This causes the warm air to rise. It will now be seen that the mouth of the Columbia and the Straits of Juan de Fuca act as conduits for the in-rush of ocean-heated air, but these are not the only factors to be taken into consideration. Puget Sound itself is a large body of ocean-heated water, much of which is changed twice every 24 hours as the tide comes in and goes out. The usual fluctuation is about six feet, but it is often much more. I have no immediate means of estimating the vast climatic influences exerted upon the surrounding country by this introduction of ocean-heated water between these ranges of mountains, upon such a stupendous scale, twice every 24 hours.

But it will readily be seen that these two ranges of mountains lifting their even, snow-clad summits into the air, coupled with the repeated withdrawal and re-introduction of ocean-heated water through these breaks in the Olympia Mountains, must bring a great inflow of heated air from the ocean, to say nothing now of the greater flood of warm air brought by the chinook over and above the summits of the mountains themselves. It will require fuller study and consideration of these factors before we can arrive at a proper estimate of all the climatic conditions that prevail here, but it may already be seen that it is neither a coast nor an ordinary inland climate, nor a valley nor a mountain climate, but that it partakes of some of the features of the four combined. The result is about the most equable climate upon the globe—neither too hot in summer nor too cold in winter, and when I come to speak of the pomology, it will be seen how the climate stimulates some of the finest bud and fruit development to be seen anywhere in the world. D. S. MARVIN.

RURAL SPECIAL REPORTS.

New York.

HORNELLSVILLE, Steuben County, August 26.—The acreage of potatoes here is about two-thirds of an average. During spring some rotted and never came up, the others have blighted badly and are now rotting. The crop will not be more than one-half of an average, and the rot may reduce it below that before digging. In hills examined, the rot on an average now affects about one potato in six or eight, and it has just begun. None will be dug before the last of September or the first of October. We are on sandy land, on the river bottom. In this town the potatoes are reported to be from one-half to two-thirds rotten. Oats and hay are about an average. J. E. P.

FRIENDSHIP, Allegany County, September 2.—The condition of potatoes is bad. They are rotting to a great extent. I do not think there will be half a crop. J. B. H.

Ohio.

CARYVILLE, Champaign County, September 5.—Much of the farming in this region is done by tenants, who, as a class, do not read much agricultural literature. The owners of the farms either own too much land or have "retired" and moved to some town, and care for the farm only for what they can get off it. Still we have a few first-class farmers, who by their industry and economy are prospering. The masses simply make a living and pay their expenses and have nothing left. This has been a poor season here—a season remarkable for its extremes. We had a mild winter, and an early, very dry and cold spring. About the middle of May wet weather set in and continued till about the 10th of July. This proved to be about the worst wet spell we have had in this region for many years, and consequently we have much poor and weedy corn, as well as poor potatoes, hay and wheat. The oat crop is rather good. The weather is now very hot and dry. Many farmers will commence sowing wheat this week. G. D.

Texas.

CIRCLEVILLE, Williamson County.—In all my life I've never seen so near a failure in potatoes. We had a very warm winter, and a great deal of rain. For weeks the fields could not be worked just at the time working them was most necessary. The early planted rotted very badly, and not more than one-fourth of a stand came up on an average, and yielded small potatoes. The second plot made a few scattering potatoes. The third did not make any. The R.-N.-Y. No. 2 was planted about March 15 in nine hills. It made fine tops, but died in July from drought. I got only two small tubers not very well matured. As a general thing, I think it would do well here. This has been a bad year for testing potatoes.

MRS. N. M.

THE FARMER'S CLUB

ANSWERS TO CORRESPONDENTS

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see if it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

ABOUT SHEEP.

J. L. W., Worcester, N. Y.—1. Will it be best for me to buy, say, 25 sheep to commence with and breed up to the required number, or buy at the start what I could keep? 2. Should I buy store sheep of the mixed breeds around here, and breed up or buy the kind I want of some sheep raiser? 3. How many sheep will eat as much as one cow? 4. How many sheep can be safely kept together? 5. When should they be bought? 6. I want information about early lambs. 7. What is a good paper devoted to sheep husbandry? 8. Can the RURAL give any more useful hints on this subject?

ANS.—1. Better purchase all you want to begin with. 2. You had better purchase large fine-wool (not pure Merinos) Michigan ewes in the Buffalo market. Then purchase a well-bred South Down, or Shropshire, Hampshire or Dorset ram. If you aim to raise very early lambs perhaps the Dorsets will be the best. Save all of the good ewe lambs until your flock is bred to the size and character you want. Feed heavily enough in the winter to mature the lambs rapidly and keep the ewes fat. Shear the ewes in January and the lambs in March. Sell all ewes to the butcher before they go to grass except those that are superlatively good. During the summer increase the flock from new purchases at Buffalo. 3. Six to seven coarse-wools and eight to nine fine-wools are equal to a cow in the amount of food consumed. 4. Fine-wooled sheep may be kept in the fields in large flocks (200-300), coarse-wool flocks should not exceed 50. 5. Buy your sheep from June to September. 6. You would better address J. S. Woodward, Secretary of New York State Agricultural Society, Albany, if you desire the latest and most reliable information in regard to purchasing, breeding, feeding and selling sheep and early lambs. 7. American Sheep Breeder, Chicago, Ill. 8. In order to improve your pastures and get the most out of your sheep, you should purchase more animals than the pastures will carry during the late summer and fall months. Feed liberally as soon as the pastures begin to decline on bran, cotton-seed meal and oil-meal combined or separately. By this method more plant food is returned to the soil than is taken off. Weeds and brambles are all stripped of their foliage by the sheep and hence must die.

"GERMAN HARES."

A Subscriber, Brighton, O.—I inclose a circular advertising "German hares," and should like to know if the statements as given are facts. They are important if true, and if not deserve a place in the Eye-Opener.

ANS.—The statements referred to are that the German hares, known also as Scotch rabbits, and Belgian hares, are very prolific, are extremely hardy, etc; that they are eagerly sought for by epicures and restaurants in New York and other cities; that they weigh from 12 to 15 pounds, and readily bring from $1.00 to $1.25 each in the New York market. Then some delusive figures are given based on their fecundity, to show that two acres of land stocked with a few pairs of German hares will produce more clear cash per year than a 100-acre farm. The most important statement (to the advertiser) is the fact that he is prepared promptly to fill all orders for breeding stock at $5 per pair. A dealer in breeding poultry, dogs, pigeons, etc., on Cortlandt Street, this city, tells us that he has been selling these hares for a long time; that his regular price is $3 per pair, and that he has numerous letters from breeders of them offering them to him at $1 per pair. This doesn't look much like selling them readily for $1 to $1.25 each. We failed to find a dealer who had ever heard of any demand for them. One German had shot them in the "Old Country" when a boy, and said they were somewhat larger than our common rabbits, a large one sometimes weighing 10 pounds. He thought they might sell at Christmas, when there was usually a great demand for game, at $1 per pair, but he said that rabbits often sold for as low as 15 cents per pair. We have no confidence in any of the statements made, excepting perhaps that with regard to their fecundity. It is a very easy matter to figure out big profits on any such scheme, but the profits usually fail to materialize.

SEEDING FOR A PERMANENT PASTURE.

J. C. O., Somerset, Ky.—I want to make permanent pasture on land now thinly set in clover and Orchard Grass: soil, thin and sandy clay mostly underlaid by stiff, red clay subsoil. When should seed be sowed? What kinds and how much of each per acre? How much and what kinds of commercial fertilizer?

ANS.—In Kentucky one can seed down for permanent pasture at any time during September. As we understand it, our inquirer does not intend to break up his thin soil, consequently the grass seed should be harrowed in with a Thomas smoothing harow. The kind of seed best adapted to his soil would be a mixture, in about equal proportions, of Meadow Fescue, Pacey's Rye Grass, Rough-stalk, Red-top, Kentucky Blue Grass, Crested Dog's tail and Timothy, at the rate of one bushel to the acre. To this mixture a sprinkling of Sweet Vernal Grass and White Clover might be added. As to what commercial fertilizers ought to be put on, we think that one barrel of kainit and one of superphosphate to the acre, sown on and harrowed in at the time of seeding, would be helpful, and that kind of fertilizing, for the sake of obtaining potash cheaply, ought to be continued as a top-dressing every alternate year after the grass is well established. If our friend can obtain good hard-wood ashes cheap, it would be best to do so and to put on about one ton to the acre instead of the kainit.

Miscellaneous Advertising.

"Herbrand" Fifth Wheel for Buggies.

CRACKED HEELS IN HORSES, ETC.

J. F. D. G., Gouverneur, N. Y.—1. What is a remedy for cracked heels on horses? 2. What is good for a horse that rubs and bites himself?

ANS.—1. If there is an offensive discharge with a strong odor—thrush—cut away all dead or diseased horn and then apply dry calomel, pressing it well into the crack, until the discharge ceases. Then keep the hoof coated once daily with the best pine tar until well grown out. If, however, there is a discharge like the pus or matter from an ordinary wound, wash out once daily with a solution of five parts of carbolic acid in 100 parts of water and apply a coating of tar after each dressing. For a simple crack in the hoof without discharge, apply a mild blister around the top of the hoof, especially above the crack, and keep the hoof coated with the tar as directed above. 2. A good dose of physic—six to eight drams of Barbadoes aloes, according to the size and condition of the animal, with an ounce of ginger, to be given in a ball or as a drench, and followed by a bran mash diet until freely purged. After being purged, a course of powders somewhat like the following can be given with advantage: one pound each of bicarbonate of soda, Glauber salts, and powdered gentian well mixed together. Dose—two table-spoonfuls twice daily on the feed.

STERILITY IN A BULL.

A. J. T., Homewood, Pa.—My three-year-old Jersey bull is not a sure calf-getter. Scarcely any of the 30 cows he has covered this season are with calf, though he has covered some four or five times. He is in fair order, being neither poor nor fat. He has been most of the time on grass pasture with the cows, though for a part of the time he has been staked out. Can anything be done for him?

ANS.—The bull is probably temporarily sterile because weakened by too much service. Judging from your history of the case, he has served the equivalent of 100 to 150 cows one service each, which is two or three times as many as a bull can usually profitably serve in a year. Keep the bull away from the cows, but give him plenty of exercise, preferably in a small field or yard by himself, or with cattle that will not come in heat. In addition to his corn fodder feed him some bran or oats twice daily. Allow him to serve one or not to exceed two cows per week, and allow only one good service to each cow. If he was a successful getter of calves last year, he will probably become fertile again after a little rest and attention, if his powers are not overtaxed, as has evidently been the case thus far during the season.

PUFFS ON YOUNG COLTS.

F. B. B., Ottawa, Mich.—Within a few days after the birth of my one-month-old colt soft bunches appeared on the outside of each front knee just below the joint. They were about as large as a hen's egg, and not tender, nor did they cause any lameness. A few days afterwards above these appeared swellings which were not quite so soft and which were tender too, if rubbed. The colt is strong and active. The stall floor was wet and slippery when the colt was born, and it had some difficulty in getting on its feet, wrenching its joints perhaps in doing so. 2. Splints also appear quite prominently low down on the legs, but do not cause lameness. What should be the treatment?

ANS.—Beyond bathing the swelling with cold water or with a mild stimulant, like arnica or camphorated spirits, we would not, without a personal examination, advise treatment at present, or as long as the colt is not lame. If the swellings do not show a tendency to disappear after a few weeks, try the application of the compound tincture of iodine, applying it once daily until the skin is slightly blistered. Later more active treatment may be demanded if the colt does not outgrow the trouble.

THE WEIGHT OF HAY IN A STACK.

H. S., Hot Springs, South Dakota.—How can I ascertain the amount of hay in a stack 40 feet long, 20 feet wide and nine feet high from the ground to the beginning of the slanting top and 14 from the apex of the sloping top to the ground?

ANS.—Hay dealers allow 512 cubic feet to the ton. This is considered accurate enough, although much depends upon the sort of hay in the stack and also the care with which it is made. Your stack contains 9,200 cubic feet. Dividing this by 512, we have a small fraction less than 18 tons; to be exact, 17.96 tons. The number of cubic feet in the stack can be found by multiplying 40 by 20 by nine feet. This gives the cubic area up to the slant. Then we have a mass 40 feet long, 20 feet wide and five feet high in the center, equal to a uniform thickness of 2½ feet. The first multiplication gives 7,200 and the second 2,000 or a total of 9,200 cubic feet.

COWS DRYING OFF.

C. B. C., Putnam, Conn.—Two of my cows have suddenly become "dry." They eat well and are apparently in good health in all respects. They are on the same pasture in which they have been all summer, and no change has been made in their feed. What is the cause, and a remedy?

ANS.—If there is no apparent cause for the "drying off," which could be accounted for by a dairyman, such as short grass, scarcity of good water, several months already in milk, injury or disease, we cannot suggest why they should have done so. Unless the cows have a previous good record, it would indicate that they were probably short milkers, and better subjects for the butcher than for the dairyman.

Miscellaneous.

J. H., Mechanicsville, N. Y.—Who makes ice plows?

ANS.—The Higganum Manufacturing Company, New York.

P. W. J., Pontiac, Mich.—What is the best apparatus for cooking feed for hogs?

ANS.—This inquiry is fully answered in this week's "symposium" on Cooking Feed. J. K. Purington of Des Moines, Iowa sells an excellent steamer.

J. J. T., Buffalo, N. Y.—I am going to plant 15 acres of winter wheat this month, and would like to try nitrate of soda or sulphate of ammonia. Can I use it with wood ashes, and bone dust, and shall I put on 200 pounds to the acre now or wait until spring before putting on the nitrate? I want to sow Timothy with the wheat.

ANS.—*Use the nitrate of soda not until spring.* The bone and ashes may be spread now. In the spring we should use equal quantities of nitrate of soda and sulphate of ammonia, rather than all of either.

J. H. L., Natrona, Pa.—My three-year-old pacing stallion had the distemper when a foal, and he has never got over the effects. Now when he drinks, some of the water comes down his nostrils, and when eating sometimes he coughs and appears to be choked; then some of his well-chewed food will come through his nostrils. Then he is all right for a while, eating and drinking without any trouble. What should be done?

ANS.—Rub the whole region of the throat once daily with the following liniment until the skin is quite well blistered: Equal parts sweet oil and strong aqua ammonia well shaken together. Repeat the blistering whenever the difficulty occurs.

Discussion.

TAP-ROOTS VS. TRANSPLANTING.

P. H. R., DOWNIEVILLE, CALIFORNIA.—In the RURAL of May 4 there is a discussion of a proposition to start an orchard by planting the seeds where the orchard trees ought to stand and grafting on the sprouts. I was much interested in the discussion, though I do not feel satisfied that what to me seems so large a subject was treated so lightly. I had proposed to adopt the same plan as S. B. H. I yet believe it by far the best way. I have about 30 acres of hillside facing the south, protected from frosts, and good enough to produce a fine body of oak timber. It is very dry. Sometimes rain does not fall on it for three or four months, yet I hope by pursuing the above plan to get trees in two or three years' time that will have roots long and strong enough to supply themselves with moisture without any aid except mulching. Can it be done? Well, not with nursery trees. Dr. Hoskins, speaking from an experience of forty years in orchard and nursery work, and backed by the experience of hundreds of others, says that trees suffer no permanent injury in transplanting. Forty years' active work and close observation ought to entitle one to be listened to deferentially, especially when such an one has much ability both natural and acquired. But able men sometimes get into grooves from which it is difficult to find exit; incorrect data and statements are accepted as true, and false conclusions are drawn, and thus is wasted much conscientious labor, and progress is retarded. It is well known that many things considered indispensable in the medical practice of 50 years ago, are now utterly condemned; and in many other callings long-cherished ideas retain their vitality because of our diffidence in attacking long established usages. Now, I have been carefully watching the growth and development of several species of young trees growing from seed, and have observed that the first thing a seed does is to start its strongest and longest root straight downward, and that the size and length of this are only limited by the space given it in which to expand. God, or Nature, makes no mistake in directing the inherent forces of matter, and would not make the tap-root the longest and strongest—a veritable underground tree—if it had not been, in the economy of tree growth, a necessity, I believe that God knows something of tree planting, and when I see these facts so definitely and constantly pointed out, it will take the evidence from hard-proved comparative experiments to shake my faith in a root system that stands in its original position and entirety. I know that a deep-rooted tree stands more firmly than one whose tap-root has been shortened; and I believe that it is far better prepared to stand drought or extreme cold. The tap-root once cut, will send out lateral branches, but never again go far downward; it is a cripple for life.

"The immense number of very aged and yet vigorous apple trees in existence which have certainly been transplanted," is offered in evidence to prove that repeated injuries to the roots cause "no permanent detriment." That such trees exist only serves to show that they will survive gross abuse—that they will live *in spite* of serious injury. That trees may suffer a suspension of vital action without loss of anything but time may be debatable; but will any one maintain that their vigor is not impaired or their chances for long life lessened by removal of their vital organs? One can easily understand that, from the nature of its surroundings, a forest tree can only live a relatively short life; but an apple tree need never die. As long as manurial values equal to the loss sustained by the soil in maturing the fruit are supplied to it, so long will it fulfill its mission and continue to expand. Nature never tires. "Pay as you go" when dealing with her, and you are making a limitless credit account in a safe bank.

It is patent that I am ignorant of many things which seem to be so trite to the RURAL correspondents as not to be worthy of mention. The "many practical difficulties" to be encountered in pursuing such a practice as proposed, do not seem tangible nor are they visible to me; neither do I know how one could get a hardy tree on which to graft if not from the seed of an iron-clad. I do not even know what is to be gained by having a long trunk. In fact, I believe that the waste of time in growing a long body is so unnecessary that I shall allow mine to branch as soon as they show a disposition to do so. I believe the proposed plan will insure a gain of two years in the early securing of fruit from the average tree; and that the standard of its vitality will be far above that of one whose growth is checked and the proper direction of whose development is destroyed. If my conclusions are as sound as my facts are suggestive, there is no danger of giving undue prominence to the discussion of this subject; nor of too great a crop of thinkers, investigators and experimenters in a field that offers so much opportunity and reward.

FUNGOUS DISEASES OF FRUIT TREES.

PROF. J. L. BUDD, AMES, IOWA.—I have read with much interest the article by Dr. Halsted in a late RURAL on the fungus of the pear, and the thought occurs that some general notes from a climatic standpoint on the fungous troubles of our orchard and small fruits may have some interest. As a probable result of the unusual extremes of the past few years in heat and moisture of air, rainfall, etc, in the prairie States, we have had an evident increase in tendency to rusts, smuts, mildews, and blights in the orchard and garden. Beyond reasonable doubt this increase of the fungi has had as much to do with our orchard losses of trees as the test winters which have been talked and written about. A few years ago the Early Richmond and English Morello Cherries, the Lombard Plum, the Ben Davis Apple, and the Flemish Beauty Pear, were considered hardy in central Iowa, but recently when the time came it was difficult to find a healthy leaf on them in August, their days became few and full of trouble. At this time the visitor can usually tell by the condition of the foliage the relative hardiness of the species and varieties on the college grounds. In the apple orchard the nearly hardy sorts, with more or less admixture of the west European types, are rarely perfect in leaf, and the fruit is more subject to scab than in the early days. On the other hand, the Duchess, Tetofsky, Whitney's No. 20, Wealthy, and dozens of other varieties of the east European race or their seedlings, have clean, perfect foliage and not a show of scab or crack of fruit. To-day we have gathered for the State Fair exhibit 90 varieites of Russian apples which do not show a trace of scab, while not a single variety of the west European race or their seedlings is free from this trouble.

In the cherry orchard every variety from the most trying portions of France, West Germany, and the coast provinces of Russia, is at this time destitute of leaves at the points of growth, and some of them are as bare as in winter on young and old wood. Yet the varieties obtained from points east of the Carpathians to the Volga show clean and perfect foliage to points of growth, except that now and then the terminal points show traces of a surface mildew like that on the lilac. In the plum orchard we have no variety left of the West European race or their seedlings. But our best native plums, such as De Soto, Wolff, Wyant, Hawkeye, Magnoketa, Forest Rose and Pottawatamie, show perfect foliage and fruit as do the thick-leaved sorts from central Russia. Simon's Plum and the Shense Apricot, coming from the dry and changeable climate of northwest China, have also perfect foliage and fruit.

In the way of pears we have nothing now left of the old standard sorts or of the Chinese pears and their crosses, which do well in New Jersey. But the Snow Pears of Northwestern China are perfect in foliage, tree and fruit, and I have hardly seen a trace of fungus on the thick leaves of the interior Russian varieties. On the other hand, the varieties from the coast provinces of Russia are now destitute of foliage. The peaches from Northwest China are here nearly hardy in tree and perfect in foliage; but nearly every specimen of fruit is scabbed on one side. On the other hand, the varieties from Bokhara in Asia are perfect in foliage and I have not seen or heard of a trace of scab on the fruit.

I give these general notes to show that in our trying climate the structure of the leaf and the epidermis of the bark and fruit has much to do with the tendency to rust, scab, etc., and that we cannot hope to do much in a general way in the successful use of fungicides. In the strawberry, raspberry, blackberry, currant, gooseberry and grape I notice the same tendency to leaf troubles in some varieties and comparative exemption in others.

COMPARATIVE PRICES OF BEEF CATTLE.

JUDGE T. C. JONES, DELAWARE, OHIO.—In a recent communication to the Ohio Farmer after speaking of the decline in price of Short-horn cattle, I said, referring to the general business of cattle-growing:—It is to be observed that the present severe depression in the market values of beef cattle and dairy products is not without a parallel in former years. During the depression in our agricultural products, beginning about the year 1840, the dressed carcasses of hogs sold as low as $2.50 to $3 per 100 pounds, while beef was still lower. In later years, say about 1859 or 1860, my recollection is that beef cattle and dairy cows were quite as cheap as they are at this time. The present depression, however, has one peculiar feature. It affects more seriously superior fat cattle of heavy weights than the inferior or lighter grades.

How do we account for this? It is true that since the discovery and universal use of petroleum and gas for illumination, the price of tallow has declined to a figure so low that its production is no longer profitable, and the taste of our people has changed so that butchers say that they find it difficult to sell well-fattened beef or mutton. This is an unaccountable condition of things, but it explains, I think, the reason why the present depression in prices as quoted in our leading markets (Chicago, Buffalo, etc.,) affects much more seriously the best cattle, the ripe and well matured stock, than the young and lean sort.

If this singular characteristic in the taste of our beef consumers is to continue, I regard it as the most discouraging feature of the present outlook. Heretofore the great argument in favor of good stock with liberal grazing and feeding has been that such cattle, however hard the markets for the light, lean and inferior sort, would always fetch prices that were fairly remunerative. But there is reason to believe that consum-

ers will not be slow to learn why it is that so much of the beef now in the market is hard, dry, and tasteless, and will demand meat full of rich juices, with high flavor, and will be willing to pay for it. But this quality is only found in cattle of good blood that are well fattened, and of suitable age; say in bullocks of half or three-quarter blood 30 to 36 months old, at which age fattened cattle should weigh 1,300 to 1,500 pounds with proper and not extravagant feeding and management.

Since the above was written, there has been a material advance in the market price of good heavy cattle as compared with the figures for inferior and light stock, caused, as I understand, by the expiration of a contract which a syndicate of exporters had made with ocean steamers for all their available space, by which this syndicate was able for a time to control the market value of export cattle.

BOGUS JELLIES.

T. GREINER, NIAGARA COUNTY, N. Y.—Yes, there is considerable demand for jellies at prices that would land in the poor-house any one fool-hardy enough to attempt meeting this demand by the manufacture of jellies from genuine fruit and good cane sugar. There is a demand for jellies that can be sold cheap, and neither grocer nor hotel-keeper nor boarding-house mistress will pay a cent more per quart for genuine fruit jelly than for the stuff made from alum, and gelatine or at best from apple refuse and the cheapest sugar, flavored with coal-tar extracts. Why should they? The cheap adulterated article answers the purpose just as well, and tickles the palates of the boarder just as much as the pure article. The consideration for the consumer's health does not count with the seller or dispenser. But such consideration should count with the authorities and law-makers. Now what's the use of talking about a prohibitory tariff on bananas and other foreign fruits, with the view of shutting off the perfectly legitimate foreign competition, so long as we allow a promising outlet for much of our surplus fruits to be entirely blocked by fraudulent illegitimate competition at home by the unrestricted, and, thus far, unopposed manufacture and sale of bogus jellies, the consumption of which can not be recommended on sanitary grounds. Here we have a case analogous to the adulteration of dairy products, only in an aggravated form. Our horticultural "oleomargarine is a mixture of nasty materials." It has driven the genuine horticultural product entirely out of the markets, and forbids its remunerative manufacture. Here, indeed, is cause for "protection." Against cheap bananas the grower of domestic fruit can in a measure protect himself, by the production of strictly first-class fruits, and by the adoption of improved modes of culture—cheapening production. Against the horrid mixtures called "fruit jellies" he is powerless, and prohibitory laws are called for. Demand for jellies? All the present demand at present prices does not justify the advice to the fruit-grower and to the house-wife to go to the trouble and the expense of making such goods. When the cheap refuse, coal-tar mixture, is done away with by the enactment of an anti-bogus jelly law, then, and not until then, it will be time to talk about the demand for fruit jellies.

FALL FEEDING OF MOWING LANDS.

P. C., MILFORD, N. H.—I never turn cattle into the mowing to feed in the fall. I would much rather cut the grass and feed the stock in the barn. I always plan to have plenty of fodder corn, and when the frost takes that then I feed barley and peas, which I sow about August 10, and I cut and feed that generally until snow comes. After the advent of freezing weather, I cut it and keep enough on hand in the barn so that it will thaw out before it is fed. There are farms near here that are pastured so closely in the fall that it is impossible for the grass to recover in the spring, and consequently the hay crop is lighter every year until the land has been seeded again. Any one can see such places in every town, and those who practice fall feeding will not readily believe the bad results of it; but, if you ask them how their grass is turning out, they will say that they have not much more than half a crop and that they don't see why it is, and if you hint to them that they pasture it too much, they will say that they think it is best to feed off some of the old stuff and mowing will be easier next year, and that it doesn't do any harm. If they think so and will use no judgment, when they can see the difference between their fields in the spring and those of their neighbor who does not fall-feed his mowing, then perhaps it is best not to advise them any more, for they will do just so again every fall while life lasts.

ISOTHERMAL LINES, NOT PARALLELS OF LATITUDE.

J. C. V., CHICAGO, ILL.—Referring to a recent note in the RURAL, by Mr. Gregory, in regard to the effect of latitude on the earliness of corn, I do not think the truth is fully stated. The question is not at all one of latitude, but one of similar degrees of heat or cold. These differ from parallels of latitude very greatly, and are governed by very many causes, such as variation of altitude, prevailing drought or rainfall, contiguous large bodies of water, etc.

To arrange for corn of one variety which will ripen a few days apart, one should study the isothermal lines.

For example, suppose corn to be planted at Madison, Wisconsin, and also at South Bend, Indiana; at these two places although 125 miles apart as to latitude, it would mature at the same season. Corn planted at the same time at Grand Haven, Michigan, on a latitude parallel with Madison, Wisconsin, would not mature until 10 days later than the same variety planted at Madison, owing to the prevalence of cool westerly winds from Lake Michigan. I think in no case could this difference in earliness of maturity be managed by following strictly the parallels of latitude, but it could be thoroughly and correctly done by planting according to parallels of similar heat or cold, that is isothermal lines.

H. A. W., CHAUTAUQUA COUNTY, N. Y.—An inquirer asks in the RURAL if it would pay to have two sets of wheels for farm wagons. If the wagon is to be used on the farm and also on the road, one should have two sets of wheels. The tires for the road wagon should be 1¾ inch, those for the farm wagon not less than six inches, and the wheels should not be over 3½ feet in diameter. There is little trouble in changing, if one is prepared with a handy jack. The wide-tired wagon can be used on the farm when it would be impossible to use the narrow-tired one to any advantage.

L. H., DANSVILLE, N. Y.—What Mr. Terry says, in speaking of shallow cultivation for potatoes on page 555 of the RURAL, prompts me to speak of my method. I have a wheel fastened to the rear of my cultivator so that the depth at which the rear teeth or those in front run can be as easily adjusted. If I wished to take either wheel off, I would remove the front one, as less damage would be done by the front teeth running deeply.

What Others Say.

FINALLY.

BUTTER AND CHEESE.—Professor Long, in a lecture before the Cirencester Chamber of Agriculture, England, as noted by Dr. Hoskins in the Vermont Watchman, said that a ton of butter takes from the soil 2.7 pounds of nitrogen, 1.58 pound of phosphoric acid, and one pound of potash, the total value of which he estimated at about 50 cents. No other product, probably, takes so small an amount of fertilizing material off from the farm. Cheese is much more exhaustive. The professor's estimate is that a ton of cheese takes from the soil 112 pounds of nitrogen, 1.58 pound of phosphoric acid and one pound of potash—valued at about $10. When the milk is sold off from the farm there go with it, in addition to what is in the cheese, 2.72 pounds of nitrogen, 1.84 pound of phosphoric acid, and 5.67 pounds of potash.....

IT is estimated by the past rate of increase of population that in 30 years hence or in 1920, the population of the U. S. will be 160,000,000. The R. N.-Y. wonders how farming will pay then.....

SULPHATE OF LIME (plaster) is recommended as better than lime to prevent potato rot.....

FARMERS of this state are cautioned by Director Collier to beware of wheat swindles.....

THE N. Y. TIMES says that it is a mistake to suppose that a plantation of young timber would not add to the selling value of a farm. People who come as recruits to farming from other business pursuits, are most apt to look at a thrifty grove of timber as of more value—as it really is—than any other equal area of land on a farm. Few men besides farmers ignore the value, as well as the beauty, of a grove or plot of woodland; and the majority of farmers are now discovering that a plantation coming on is a good thing to have on the farm. A row of trees along each side of the road, if nothing more can be provided for, will much enhance the value of the land, and it certainly adds to the beauty of the landscape, which is an element of value in the estimation of any reasonable purchaser....

J. H. HALE pronounces the Oldmixon the best eating peach that grows. He planted more largely of it than of any of the others, and expects to have not less than 5,000 baskets of this one variety. He finds that one orchard of this variety on light sandy soil is ripening its fruit 10 days ahead of other orchards, and these will all be out of the way before the others come on, and so prolong the season 10 days.....

SECRETARY OF AGRICULTURE RUSK favors Chicago for the World's Fair in 1892 and he gives several excellent reasons therefor. Utterly regardless of local interests, or the interests of any State, the R. N.-Y. wants the great fair to be held where it will best serve the interests of the entire country....

THE LONDON GARDEN calls our desire to increase the size of flowers a "crazy fashion." It mentions the petunia, marigold, pansy, hollyhock and balsam as among the flowers which have suffered most by this sort of "improvement."....

PROPAGATE strawberries by selecting the most vigorous runners is the good advice of C. L. JONES in Garden and Forest.....

IN putting up grape juice, catsups or anything of the kind which is to keep in an unfermented condition remember two things: Have the liquid boiling hot and fill the bottles full. Of course the cork displaces some of the liquid. Be sure the corks are sound and air-tight. When the liquid cools, it will contract leaving a small space between it and the cork. It is a safe precaution to dip the corks in some kind of wax.....

PROF. J. L. BUDD of Ames, Iowa, in reply to a question, states in the Farmer's Review that during the past 20 years he has watched the behavior of the peach when budded on young stocks of the Wild Goose—Miner and other Chickasaw varieties—and he has about reached the belief that in some respects they are preferable to peach roots. He says he has not known the borer to attack the peach wood when budded on these stocks above the crown. He has thought that the peach wood ripened up more perfectly on these stocks, and that for this reason the fruit buds would endure a lower winter temperature. He has believed that the peach would do well on this stock on soils where it would nearly fail on peach roots.....

ABSTRACTS.

——NEW YORK HERALD: "The surest way to please is to forget one's self and think only of others."

——"THE reason some men can't make both ends meet is because they are too busily engaged in making one end drink."

LAUGH, and the world laughs with you;
Weep, and you weep alone,

——C. L. ALLEN in American Garden: "As cut flowers for table decoration, the nasturtium has but few equals, and for garden display, five cents' worth of seed will produce a greater and more pleasing effect than $25 invested in bedding plants, besides a bountiful supply for pickles, than which there are none better."

——BOSTON COURIER: "Domestic skeletons are usually formed of the bones of contention."

——HENRY STEWART: "As a plant grows most vigorously when its roots have a firm hold upon the soil, so a farmer is most prosperous when he feels firmly attached to his farm and thinks of it as a life interest to him."

——N. Y. TIMES: "All grain bins should be made of such sizes as will hold an even number of bushels, and by having marks around the bins inside, the contents of a partly-filled bin may be known. Thus, if the floor of a bin is 50 inches long by 43 wide inside, every inch in depth equals one bushel. A bin 100 inches long by 43 wide holds two bushels in each inch of depth. Thus a bin may be made to measure itself by marking the depth in inches on the ends and sides and leveling the grain."

——AMERICAN FLORIST: "That the catalogue business is being overdone there can be little doubt, and in the present fierce competition it will soon be a case of the survival of the fittest. And we predict that the survivors will be those who have honest illustrations and descriptions in their catalogues, who eschew all bombast and exaggerations, and who conduct their business in a square, straightforward way, getting a fair price for a good article which will give satisfaction to the buyer."

——LIFE: "LOVER (*ardently*): 'I love the very ground you tread on.'

HEIRESS: 'I thought it was the farm you were after.'"

——FARM JOURNAL: "When it takes five quarts of milk to pay for one drink of whiskey it pays to drink milk and let the whiskey alone. It pays always to let whiskey alone."

——"IF an insect gets into the ear drown him in oil and then wash him out with warm water."

——N. Y. HERALD: "Good crops are the basis of our wealth and general well being, and the yield this year is so grand as to warrant a day of special thanksgiving. The shortage in the harvests abroad assures a good demand for our surplus cereals, and their export, together with the continued investment of foreign funds in manufactures here, should bring an influx of gold later on."

——N. Y. SUN: "If the great consolidated farmers' trust succeeds in controlling the cotton crop, the flag of monopoly will float defiantly over cotton States. It is amusing to see men denouncing monopoly and at the same time trying to get a monopoly; but such is the humor of human nature."

——ORANGE COUNTY FARMER: "We have fattened calves in from six to seven weeks' time, exclusively on sweet skim-milk, that weighed over 200 pounds, and made very nice veal at that. A little linseed-oil meal added, however, improves the milk for that purpose."

Miscellaneous Advertising.

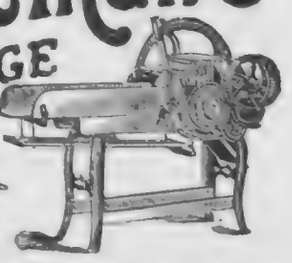
Hood's Sarsaparilla 100 Doses One Dollar

Scrofula in its severest forms, salt rheum, and all other blood diseases, are cured by the great blood purifier, Hood's Sarsaparilla. The voluntary statements of cures by this medicine are really wonderful. Send for particulars to C. I. Hood & Co., proprietors Hood's Sarsaparilla, Lowell, Mass.

NOTHING ON EARTH WILL MAKE HENS LAY LIKE SHERIDAN'S CONDITION POWDER

Highly concentrated. Dose small. In quantity costs less than one-tenth cent a day per hen. Prevents and cures all diseases. If you can't get it, we send by mail post-paid, One pack. 25c. Five $1. 2 1-4 lb. can $1.20; 5 cans $5. Express paid. Testimonials free. Send stamps or cash. Farmers' Poultry Guide (price 25c.) free with $1.00 orders or more. I. S. JOHNSON & CO., Boston, Mass.

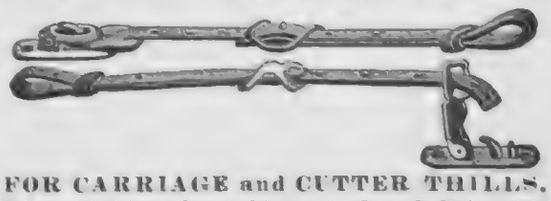
Freeman's ENSILAGE AND FEED CUTTER



The Strongest, Most Durable, Handsomest, Easiest Running and in every way THE BEST FEED CUTTER made. All Sizes, for Hand or Power. Carriers any length. For Low Prices and Best Discounts, send for Illustrated Catalogue "E." Valuable "Ensilage Encyclopedia" free to all who mention this paper. Also Manufacturers of the Celebrated Centennial Fanning Mill.

S. Freeman & Sons Mfg. Co., Racine, Wis.

SHERWIN BROS'. SAFETY HOLDBACKS



FOR CARRIAGE and CUTTER THILLS. Self-unhitching—finest thing out. Sample Pair, with Straps, $1.25, prepaid. Agents wanted. Address

SHERWIN BROS., Brandon, Wis., or Lincoln, Neb.

KELLY GRINDING DUPLEX MILL. SEND FOR CATALOGUE

SPRINGFIELD ENGINE & THRESHER CO., SPRINGFIELD, O.

THE
RURAL NEW-YORKER,
(34 PARK ROW, NEW YORK),

A National Journal for Country and Suburban Homes.

Conducted by
ELBERT S. CARMAN.

SATURDAY, SEPTEMBER 21, 1889.

PROGRESS!

THIS week the RURAL NEW-YORKER, as regards the quality and weight of the paper upon which it is printed, and in its general make-up, will show its readers what it will be during the rest of the year, and, indeed, for the future, or, at least, until further improvements shall be made.

No back steps, friends. When the R. N.-Y. lowers its standard of excellence, its present editors will have stepped down and out.

A SUBSCRIBER in Indiana, in renewing his subscription, says: "The RURAL *is good enough to pay for*; if I knew of any higher compliment to pay, I would pay it." This compliment is entirely satisfactory to the R. N.-Y.

TRY the Berckmans Grape. It is much like the Delaware, but this season, while the latter has shed all its leaves and the berries can not ripen, the Berckmans has ripened perfectly. The vine is perfectly healthy, the bunches compact, of the color of Delaware, a little larger in size and of much the same quality.

THE next issue of the R. N.-Y. will be a notable one. It will be the regular Premium List Number. We shall offer superior inducements to our friends this year to help increase the RURAL'S circulation. Then we shall print the picture of Mr. Terry's farm implements. This picture will please everybody. We shall also have six short symposiums on important and interesting topics. On the whole, it will be a fine number to show your neighbors how far the R. N.-Y. is from being asleep.

THERE was a walking contest for horses at the Ohio State Fair last week. A track 124 rods long was used. The horses were hitched, one at a time, to an express wagon loaded with about 1,000 pounds of coal. The first prize was won by a mare which walked this distance, hauling the load, in four minutes and 10 seconds. This contest was, as we understand, organized and carried out by the Ohio Farmer. It is an excellent idea and we hope this walking contest will be introduced at all our fairs. "The best farm pace is a walk." Breeders of draft stallions are taking hold of this matter as our readers will see in a week or so.

THE R. N.-Y's. great expectations of the present season have, for the most part, been knocked to slivers, to speak in a way not quite elegant. But among the failures a success or so may be recorded. Our wheat and oat crops were among the largest ever raised at the R. N.-Y. Farm, while there is now little doubt that the corn yield (there are five acres) will be fully as large as that of the celebrated crop grown there eight years ago. One measured acre received fertilizer only; another fertilizer and farm manure; the rest farm manure. The outcome will be placed before our readers in due time. The variety is Chester County Mammoth.

ONE story told by the dressed-beef men is to the effect that their trade has been a benefit to the people because the public now use more of the better parts of the carcass. This, they say, accounts for the fact that prices for this sort of beef have not been reduced. This claim is absolute nonsense. The R. N.-Y. has consulted dozens of local butchers on this point. Prices for no kinds of meats have been reduced. No parts of the carcass are thrown away, and there is just as great a demand for the poorer cuts of beef as there ever was. Live cattle are lower in price than they were before the dressed-beef trade was developed, while the consumers are called upon to pay just as much as they ever did. Where does the difference in price go to? That is what the American people want to find out.

MINNESOTA expects a large influx of desirable agricultural settlers as soon as the 3,000,000 acres lately sold by the Chippewa Indians to the government are thrown open to settlement. The lands surrendered include Leech Lake, 94,449 acres; Lake Winnebagshish, 320,000 acres; Mille Lac, 61,014 acres; Fond du Lac, 100,121 acres; Grand Portage, 5,840 acres, Bort Fort, 107,509 acres, and about 2,250,000 acres in the Red Lake and White Earth Reservations. The total Indian population of the various reservations is about 6,300, of whom 4,670 are on the White Earth, Leech Lake and Red Lake Reservations. The Indians of these three reservations are the most industrious, and self-supporting, and their land is, on the whole, considered the best; that of the Leech Lake, Winnebagshish and Mille Lac Indians being much the worst, as it is subject to overflow owing to the recent erection of a great reservoir dam on the head-waters of the Mississippi. The land will be reserved entirely for homestead settlement, with the exception of town sites, but cannot be opened by the President's proclamation for many months to come.

$25.

TWENTY-FIVE dollars are offered by the R. N.-Y. as follows: Fifteen dollars for the largest and best shaped R. N.-Y. No. 2; $10 for the second-best. Description and weight should be sent in before November next. Those only who may be entitled to one or the other of the above prizes, *as judged by their own reports*, will be asked to forward the specimens to this office.

THE DOMINION AND THE UNION.

BY far too little is known in the United States with regard to Canadian affairs. While every trivial incident in the daily history of Europe is flashed under the Atlantic and finds its way into newspapers in every corner of this country, how many Americans, except perhaps those living along the border, ever read anything about their northern neighbors? Yet in race, institutions and interests, Americans and Canadians have far more in common than any other people on the globe, and should feel a warmer interest in each others' welfare. Isn't it time to start a new policy in this respect? Recent statistics of the trade and navigation of the Dominion during the fiscal year of 1888, show, beyond question, that the most profitable and natural market for the products of Dominion is in the Union. During that year Canada sold to the United States $42,512,065 worth of goods and to Great Britain $42,094,984 worth, showing an excess of half a million dollars in favor of this country. The imports from the United States were $48,481,848—$9,000,000 greater than those from Great Britain. The volume of trade with the Mother Country—imports and exports—was smaller in 1888 than in any other year since confederation, in 1857; while the transactions with this country were larger than in any preceding year except in 1882 and 1883. One-half the Canadian exports of lumber and other forest products are disposed of in the United States; so are over three-fourths of the minerals, two-thirds of the agricultural products, nearly one-half of the fish; 40 per cent. of the manufactured articles, and practically all the surplus miscellaneous articles. As the two neighbors are naturally the best customers of each other; why shouldn't they want to know more of each other, and take an interest in each other's prosperity?

THE AMERICAN BEEF SUPPLY.

THE forthcoming report of the Bureau of Animal Industy will contain a report of the investigations made of late years by the Department of Agriculture to ascertain the number of cattle in this country. For a number of years past beef growers have witnessed a steady decline in prices. What caused this decline and what are the prospects for future trade? These are questions of vital importance to stockmen, and they are the questions which the Department has endeavored to answer. The pith of the report is contained in the following summary:

"The future tendency of prices with cattle will probably be to advance on account of the improbability of increasing the stock of cattle as rapidly as the population is augmenting. But this advance will be slow and uncertain for a number of years. It will be at least three years before the stock of cattle has been reduced to the proportion, as compared to population which existed in 1878, and then the mean price of steers was but $4.25 per 100 pounds, or 82 cents less than in 1888. In other words, the prices of steers for several years in the future will depend more upon the prices of hogs, upon the value of the exports of cattle and beef products, and upon the proportion of steers marketed, than upon any changes likely to occur in the number of cattle per 1,000 of population which exist in the country."

This "proportion of cattle" to population is not a safe guide in making estimates of the amount of beef in the country. The beef obtained from a given number of cattle is considerably larger than it was a few years ago. This is due to the introduction of thoroughbred stock, resulting in grades that are marketed younger, weigh more and yield an increased proportion of edible meats. The Department finds that the prices paid for steers have always followed the prices of hogs and of corn up or down. We hope the Department's prophecy will prove true and that cattle growing will once more prove profitable.

TARE ON COTTON BAGGING.

A HIGHLY important convention of the Cotton Exchanges of the country was held in New Orleans last Wednesday. Delegates from all the principal cotton markets of the country were present, and the Commissioners of Agriculture from the Southern States and representatives of the Farmers' Alliance were admitted to seats on the floor. The chief subject of discussion was the difference in tare in various markets in the matter of cotton bale coverings. Great importance has of late been attached to this question by cotton-growers and dealers on account of the wide introduction of various substitutes for jute bagging. After numerous experiments with other materials, a coarse form of cotton-sheeting made from low grades of cotton has been generally selected as at once the cheapest and most effective. By the use of this, a profitable home market will be opened for staple of poor quality, which will have a tendency to enhance the prices of better grades in other markets, and many millions of dollars that have hitherto been sent abroad every year for raw or manufactured jute will be kept at home.

The tare on jute bagging has always been so excessive that it is estimated that in this item alone the Cotton States have been cheated out of $75,000,000 since the war. The new kind of bagging is much lighter than the old, and at least a proportionate reduction of tare should be allowed on bales on which it is used. This has not hitherto been allowed in most markets. After a lengthy discussion it was unanimously resolved that "after October 1, 1889, all cotton shall be sold by net weight, allowing 24 pounds off gross weight for tare on jute-bagging-covered bales, and 16 pounds off for tare on all cotton-covered bales; the cotton covering to be of standard weight—three-quarters of a pound to the yard." If the cotton-growers will follow the advice of the Farmers' Alliance by sending their cotton only to points where this tare is in operation, they will save millions for their section.

COOKING FEED.

THE "practical men" have their inning this week and it must be admitted that they make a good case in favor of cooking food for swine; and their experience does not necessarily cast any discredit on the results of experiments at our experiment stations. These experiments showed that there was not enough gain made in feeding cooked grain to pay for the cooking. This was the only point taken into consideration, and we are not informed that the stations used the most economical apparatus for cooking the food. Aside from the simple question as to whether a peck of raw corn-meal will make more pork than the same peck of meal made into "pudding," the men who discuss the question in this week's RURAL make three claims.

1. The warm food is more palatable and comfortable for the hogs, particularly in winter.

2. Cooking enlarges the list of substances that can be profitably fed to hogs. Without it one cannot obtain the full feeding value of turnips, cabbage, pumpkins and similar foods. It is also claimed that hotel swill will be made more valuable by cooking it with other substances.

3. Clover hay, thoroughly steamed and fed warm in winter provides an excellent substitute for pasturage that can be obtained in no other way.

By means of his feed steamer Mr. Pendleton is enabled to utilize his cabbages and cracker sweepings. He obtains his profit from the utilization of what would otherwise become a waste product. Mr. Coultas finds that his steamer adds considerable value to his clover hay. In fact, it seems to the R. N.-Y. that the chief value of this practice will be found in the utilization of other products than grain. Some years ago the writer fed chopped and steamed corn-stalks to a horse with very satisfactory results. The stalks were run through a cutter, placed in a barrel and steamed by pouring boiling water on them. An old horse ate them greedily. When the stalks were given him uncut he was unable to eat them. Would not bright, well-cured stalks treated in this way equal silage in feeding value? Cooking feed in one of the modern steamers is quite a different matter from the old plan of watching a big kettle.

I believe that the waste of time in growing a long body is so unnecessary that I shall allow my fruit trees to branch as soon as they show a disposition to do so.—P. H. R., page 626.

BREVITIES.

PROGRESS.

THERE is an extra crop of roots in the country this fall.

REPORTS of the R. N.-Y.'s Women's Potato contest are coming in freely.

BLIGHTED potatoes! That is the cry of many of our Eastern correspondents.

A GOOD deal of the progress of the world is due to the fact that we preach what we do not practice. There are really very few who do practice what they preach.

A SINGLE plant of another variety of dwarf Lima bean is before us. The pods are as large as those of the large pole Lima. Illustrations of each from nature will be presented in a week or so.

FARMERS in the hay districts of New Jersey are becoming more and more inclined to give up wheat. The grain hardly pays them, and many have come to believe that the crop is not needed in securing a good seeding of grass.

THE shorter the time between the picking of a vegetable and the eating of it the better the flavor. This applies most particularly to Lima Beans and sweet corn. It is much the same with an egg. Eat one five minutes after it is laid and see!

ANTICIPATING a dry season, a good many farmers planted fodder corn. The pastures have kept up so well that they have had little use for the green fodder. Now it should be cut and nicely cured. Thus treated it is as good as hay for the cows.

THE statement recently made by Prof. Halsted and Dr. Scribner, that potatoes from rot-infested fields or sections should not be used seems likely to lead to a very lively discussion. Readers of the R. N.-Y. will have the full benefit of it. We shall give the views not only of scientists who have studied the potato carefully and watched the development of the rot, but also of the veteran potato growers who have had practical experience with all sorts of seeds and seasons. If there is anything to be learned about the matter, the R. N.-Y. will have it.

Indust'l Societies.

THE FLORISTS AT BUFFALO.

[RURAL SPECIAL REPORT.]

"The florists of the future;" glass insurance; abolition of duty on foreign bulbs; exaggerated catalogue cuts; value of a new rose; officers elected; a "national experimental garden;" killing grubs in greenhouses, having a "good time."

THE fifth annual meeting of the Society of American Florists at Buffalo, was largely attended, and was very interesting. Members were present from all parts of the country and from Canada. The Mayor of Buffalo gave an address of welcome. President J. N. May delivered the usual address, discussing many questions of interest to florists. The young assistants, who are to be the florists of the future, should be thoroughly and systematically educated both by precept and example. To be a successful florist a young man should have a fair school education, and a natural taste and love for flowers. This, combined with a good business training and a strict application, will produce the desired result in most cases. The renaming of old varieties of plants, and selling them for novelties at high prices was very mildly denounced as objectionable. The work of the Florists' Hail Association was commended. June 1, last, there were over 1,200,000 feet of glass insured. The system seems to be very popular, especially in localities where hail-storms are of frequent occurrence.

The reports of the secretary and treasurer showed that the society is in a prosperous condition. Peter Henderson made a report as chairman of a committee, recommending an effort on the part of the society to secure the abolition of the duty of 20 per cent. on imported bulbs. The fact was brought out that tulip bulbs were being successfully grown in several States. A matter of considerable interest to all who are in the habit of dealing with firms who publish catalogues, was the recommendation of the committee on "Exaggeration of Cuts in Catalogues" that catalogue men be invited to submit their illustrations to the executive committee or a sub-committee with actual specimens of the objects illustrated, and if found to be true to nature, that a certificate to such effect be issued to each for use in his catalogue. This created a very animated discussion, and the matter was referred to the executive committee with power to act upon it as it saw fit.

W. C. Barry read a very carefully prepared paper on "Roses." During the discussion following, the belief was expressed that the value of a new rose was too often decided by its adaptability for forcing. Roses are needed fully as much for planting out. Mr. Hill expressed himself as pleased with Wootton. Boston was chosen as the place for the next meeting of the convention, after which the following officers were selected for the ensuing year:

President, J. M. Jordan, St. Louis; vice-president, M. H. Norton, Boston; secretary, Wm. J. Stewart, Boston; treasurer, M. A. Hunt, Terre Haute, Ind. John Thorpe read a paper favoring the idea of a national experiment garden, and an attempt will be made to get an appropriation from Congress for that purpose. A method of heating the soil for greenhouse benches to kill the grubs was given by Mr. Carmody. It can be done very rapidly by piling the soil on steam-pipes suitably arranged. The fact was stated that the season of blooming of many summer flowers could be prolonged by picking off all the blooms so as to prevent the plant from exhausting itself by perfecting seed. It was recommended to nip the points of dahlias, thus inducing free branching. A committee appointed for the purpose reported a plan for protecting the society from dishonest dealers.

William McMillan, superintendent of the Buffalo parks, read a paper on Landscape Gardening, which ridiculed the craze for the artificial and abnormal in gardening. On Friday morning the society visited Niagara Falls, on a special train, returning in time for an elegant repast in Music Hall. After this was disposed of, the society entered carriages and were driven through the streets and parks of Buffalo. The "National Flower Committee" declined to commit itself by naming any particular flower. The National Chrysanthemum Society was organized. The $100 prize offered by Peter Henderson for the best herbarium of native plants was awarded to G. W. Oliver, Washington, D. C. J. H. Butterfoos, Lambertville, N. J., had the second best, and it was so good that it was awarded a second prize of $50 by Mr. Henderson. There was a large display of cut flowers, heaters of various kinds, and other paraphernalia of the trade.

F. H. V.

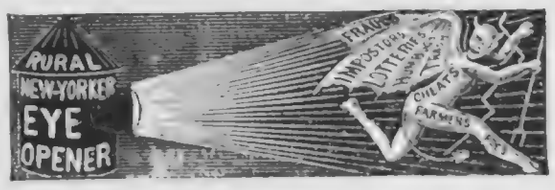
NEW ENGLAND FAIR.

(RURAL SPECIAL REPORT.)

THE 26th annual fair of the New England Agricultural Society was held at Worcester, Mass., on the 3rd, 4th, 5th and 6th of September. The weather was exceptionally fine, the attendance unprecedented and the exhibition all that could be desired. The cattle sheds were filled to overflowing. Nearly all the leading breeds were represented. A fine herd of the Dutch belted cattle was greatly admired. The Swiss also received a good deal of attention. The dairy contests were exciting and interesting. In the building devoted to dairy products, a "baby" De Laval separator was shown and its method of operation explained. It is just the thing for a small herd, say of eight or 10 cows. The tent devoted to the Patrons of Husbandry was visited by members of the order and a number of excellent speeches were made in it and attentively listened to. Domestic articles and fruits were exhibited in the Main building, but the aisles were too narrow to accommodate the crowd and a critical examination of the exhibit was impossible. Messrs. Stephen Hoyt's Sons showed some fine specimens of the Green Mountain Grape and of their new strawberry, the Yale. The vegetable tent was well filled. The show of potatoes and corn was unquestionably the finest ever made in New England. The implement buildings were next in order. They were under the charge of Mr. Curtis, the efficient manager of the Richardson Manufacturing Co. The exhibit was a good one. Such old and reliable firms as the Ames Plow Company; the Belcher & Taylor Company; the Vermont Farm Machine Company; Richardson Manufacturing Company; and the Higganum Manufacturing Company showed a full line of their well known implements. Among the novelties were Hill's milk aerator, a machine for forcing air through milk and removing all noxious odors. The Ruggles cultivator is a hand cultivator arranged on the principle of the disk-harrows. It is unquestionably a valuable implement.

The general management was good, but the presence of the fakirs who occupied a large portion of the available space and who attracted far more attention than the legitimate portion of the exhibit, was a deplorable feature. The facilities for getting visitors to and from the depot were miserably inadequate and horse and chariot racing attracted far too much attention. On the whole, however, it was a good fair and worthy of the enormous patronage it received.

J. H. G.



FRAUDS UPON FARMERS IN THE COUNTRY.

AT no time within the Eye-Opener's remembrance have swindlers preyed so heavily on farmers as they have been doing of late, judging by the exposures of their various misdoings in the public press in different parts of the country. Their modes of swindling are substantially the same that have proved successful for years, and which have been exposed over and over again in this department. The best way to keep our old readers in mind of the tricks of the tribe and put our new readers in mind of them, is to give them an occasional specimen of the numerous instances in which each kind of swindle has been successfully practiced. The swindle the success of which depends on the pretended desire of the operators to purchase a farm has been outrageously successful of late. The papers that come to the Eye-Opener's notice contain numerous accounts of such frauds, and he sees only comparatively few of all published, and a large number of cases never find their way to the papers. Hundreds of such swindles must therefore be perpetrated every year in the country at large, and the sums lost are generally quite heavy. As a rule with few exceptions, old men are the victims! There are three principal reasons for this: First, it is not until men gullible enough to be swindled in this way have grown old that they have laid by enough to make it an object to the rascals to go to the trouble of cheating them out of their hoards; second, old men are often more credulous, self-sufficient, and greedy than younger men, and, third, they are less able to take prompt and vigorous measures for recovering the property when lost, and punishing the swindlers, and hence are all the more likely to be selected as victims.

Among the dozen or more cases noticed by the Eye-Opener within the last month, the latest successful one is that of Joel S. Ordway, who lives at Loudon, near Concord, N. H. Joel is a well-to-do farmer, 80 years old, and for some time he has wanted to sell his farm. Last Monday, September 9, a nice-looking man called on him ostensibly to bargain for its purchase. After considerable talk, the glib-tongued stranger left, promising to call again. Early next forenoon he drove into Mr. Ordway's yard and prevailed on him to go to Concord where the old man was induced to draw $9,500 from the bank to prove to the prospective customer that he was a responsible man and able to support his title to the farm. The pair then started to drive back to the farm, but when about a mile from the place, they met the indispensable confederate—a young man who got into conversation with Mr. Ordway's companion. The inevitable game of cards was suggested, and the team was stopped, and Ordway's companion and the stranger began to play. The former soon lost $10,000 apparently, and asked Ordway to loan him the $9,500 to win the money back. Had he done so the brace of rascals would have straightway driven merrily off. He refused, however, whereupon one of the men held a revolver to his head while the other took the money. They then drove rapidly away, leaving the despoiled and disconsolate farmer alone on the highway. He walked to the village of Loudon, from which he was taken to Concord, where he told the police of his loss. By this time the swindlers and highwaymen had a good start. One is described as smooth-faced and about 30 years old, while the other had a light mustache and was not over 20. Of course, they'll attempt the same game again, though probably not for some time, if ever, in that neighborhood. In all such cases, plans are carefully laid beforehand. In this instance, the character of old man Ordway, the fact that he had a large cash deposit in the bank and the best place for the meeting of the confederates and the despoiling of their victim had all been ascertained and discussed in advance. Of course it's an old, old swindle, but, alas! old, old swindles always find fresh, new dupes.

A variation of the game was played, the other day, on W. W. Johnson, a wealthy farmer living two miles south of Hillsdale, Michigan. He was approached by a fine-looking man who wanted to buy his farm, with which he expressed himself highly pleased. The two men took a walk to view the property. On their way back to the house, they met an apparent stranger to both, who appeared to be intoxicated. He showed a large sum of money and engaged the would-be land buyer in a game of three-card monte, losing apparently $10,000 to him. It was then suggested that Mr. Johnson should take a hand, and seeing his "friend" so successful, he couldn't resist the temptation to do so. He went to Hillsdale, drew $2,000 from the bank and returned home. The game then proceeded, and in a short time Johnson's money was all in the common pile with that of the others. In the division, he took a package which he supposed contained money for the full amount of his stake and winnings, and the others departed. Too late, foolish Mr. Johnson found that the package contained sawdust. In a pile of clippings relating to similar frauds of recent date, the *modus operandi*, North and South, East and West is always substantially the same. How should such frauds be avoided? Well, in the sale of real estate it is always safest to deal through a responsible lawyer. If one is unwilling to do this, he should always consult his wife before taking any important step in the matter. Wherever the machinations of such rascals have been defeated, in three cases out of four, their discomfiture has been due to the wife's summary interposition.

Various.

FACTS FROM FARMERS.

FARM FIGURING.—If I were to state what I had found the most profitable during the past season's work, I should say that a few sums in mental arithmetic, worked out while in the field, had yielded the highest rate of interest, considering the capital invested. Every year I am led to realize more fully the importance of making estimates on the cost of producing and the probable income from different crops, not forgetting to make liberal allowances for loss by poor seasons, insects, etc., one of more of which are pretty sure to come. The contractor and builder first figures out carefully the cost of material and labor, then adds a certain per cent. for possible error or changes in price of material before accepting the contract for a building, or making a bid. With the small margin on farm products the farmer must figure carefully the cost from the light of past experience, and then raise the crops that promise the surest results and largest profits. I could point out many cases in my own experience during the past season, where a little calculation was the source of profit, where otherwise there would have been a loss, and what farmer cannot? I have found that I could save $25 by changing the crop I had planned to raise on a certain piece of ground, and it took but a few minutes to do the figuring. For that large, fine-looking cow that every one admired when looking at my herd, and of whose yield, when fresh, I used to boast, I have recently made an appointment at the slaughter-pen. I found her column on my milk record for the year, blank for too many months and her average correspondingly low. She did not pay for her keep. But I hear some one say it's a "heap of work" to weigh every cow's milk twice a day. Not so very much I say, but it's a "heap of work" to make a comfortable living nowadays if we do not do it, and many more small things that decide where the money comes from. But there are many who think such care causes too much trouble. Lay out your plans for the season's work only after careful calculation, but when changes of season warrant, do not hesitate to change your tactics to take advantage of an excessively dry or wet season. We ought to be able to state the exact amount of each product we raise in pounds or bushels, and the cost of producing it, till the money is in our hands. When this is done, there will be a new era in farming, compared to which the introduction of the silo is a small matter. Some of these little examples will show you results simply astounding, and I can see you carefully working them over again with pencil and paper, thinking surely you have made a mistake somewhere. I have worked some of the examples more than twice before I could be convinced, in my own mind, that I had made no mistake. Finding the result was correct often made me feel cheaper than to have found a mistake in adding or multiplying.

E. A. BISHOP.

Talladega County, Ala.

AN IDAHO NECTARINE.—I send by this day's mail a registered package from Boise County, Idaho. It contains a smooth-skinned peach for inspection. The tree resembles a peach in every respect. It is a seedling. The seed was from a peach tree in a neighbor's orchard. This neighbor's tree has never had any other than the rough-skinned peach of a fine rich color, and good flavor. There are no nectarine trees in the orchard or nearer than 25 miles. The peach or nectarine that I send is of only an average size, as there are others that are larger and some that are smaller. The skin is smooth and of a bright rich color and shines as though it had been polished. When ripe it is of a delicate green, splashed with peach red, the red often predominating. The flavor is rich and sweet and exceedingly inviting. The tree is six years old with foliage of a rich green color and very healthy. The tree spreads out and covers the ground like the Baldwin Apple tree. From all appearances it has a third more foliage than the peach trees near by. It is exceedingly hardy, having passed through our severe winter of 1887-8 when the mercury in the thermometer went down to 35 degrees below zero, Fahr. Other peach trees were killed while this one was not injured in any way, unless the fruit buds were injured, as this year is its first in fruit. The fruit on the tree will not be eatable before the middle of August. The one I send weighs 2½ ounces.

A. L. RINEARSON.

R. N.-Y.—This is a nectarine, in color and quality as above described. The nectarine is simply a peach with a glossy skin varying in hardiness and habit of tree, as all seedlings vary.

TWO POTATOES.—I sent Davenport's Early Thoroughbred and White Early Ohio

together with Early Polaris and other choice early varieties to a large seed house in England to test in 1887. The report came in that the White Early Ohio was a great yielder and the quality fine; the Davenport Thoroughbred a good yielder and the quality extra and better than that of most American potatoes sent to England. These two stood at the head. I have tested them for the last five years, and I find them superior in merit. They are from one to two weeks earlier than the Rose; their superior cooking and eating qualities are unanimously commended as well as their compact growth in the hill and their freedom from disease. Quite a number of our potato experts have tested them beside the Rose, and the reports are that in quality, hardiness, earliness and yield they far surpass that celebrated variety. They will be a great boon to market gardeners and I am confident whoever tests them once, will never give them up. O. H. A.

Charlotte, Vt.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

WHAT a relief it is to wear straight gowns without such a quantity of heavy drapery! Just notice the difference in weight between one of the older draped skirts, and one of the straight gowns now in vogue. The lighter gown is incomparably better, as far as health is concerned, apart from the convenience. Although it is said that the Directoire modes will soon be out of style, probably because they have been too popular, there is no doubt that comparatively plain straight skirts will still hold popular favor.

* * *

COLORS seem to vary but little. Green in all shades still seems likely to hold high rank among fashionable colors. Red will be popular too; the light terra-cottas have become vulgar, but some darker shades will be well worn, both in terra-cotta and mahogany. Other richer reds will be favored; a new terra-cotta tint is Eiffel red. Ashes of lilac is another new color—a soft, almost indescribable grayish tint with a suggestion of lavender. Another new color is Edison green, an electric shade copied from the light thrown on fountains. This is seen in small feathers and ostrich tips.

* * *

HARPER'S BAZAR gives some very useful suggestions for a sewing-room, which will bear repetition. Of course, we don't all possess a spare room which may be put to this purpose, but whenever it is possible a room devoted entirely to such work will be found a great comfort. For a plain, serviceable family sewing-room, the floor should be covered with linoleum; its cork lining makes it warm, and there is no fear that snips or threads will adhere. The furniture consists of a large folding cutting table, a dress form, a sewing machine, and several low chairs, a lapboard, and a large scrap basket. A three-leaved screen is suggested, to secure privacy during fitting. A great convenience for this room, suggested by the same authority is a sort of cabinet for such trifles as buttons, thread, tape, pins, etc. To make it, take one of the smooth boards on which dry goods are rolled. Procure three or four cigar boxes about two inches deep. Remove the lids from all but one. Screw these boxes lengthwise across the board, one above the other, leaving that with a lid on top. Leave enough space between them to comfortably insert the hand. Treat the whole arrangement to a coat of walnut stain, and put two screw eyes at the top to hang it up by. Across the bottom put four brass hooks, on which to hang trifles.

The proper pincushion for a home dressmaker is a crescent, ten inches long, and three inches wide at the broadest part. It must be covered with stout linen, and stuffed with bran. At either end is a tape string, so that it may be tied around the waist while in use. The sewing-room is not complete without a stock of "notions." Pins, both black and white, needles of all sizes, machine supplies, tape, hooks and eyes, and standard buttons should always be in stock, especially in a country house, where needs cannot be supplied at a moment's notice. It is a very good plan, when buying braid for a skirt, to buy two pieces instead of one, so there is no trouble about matching when the braid is to be removed.

OUT-DOOR STUDIES.

II.

STUDYING BY ANALYSIS.

WHEN one begins to know a few flowers by sight and name, one begins to ask *why* this is a ranunculus and that an epigæa; why an elm tree and a nettle should belong to the same order—in fact, we begin to think about the bare scientific skeleton which we cover with so much beauty. To understand analytical botany, we ought to begin with something we already know, just as we dissect or amplify our conjugations and declensions before attacking Virgil.

The artificial classification of plants introduced by Linnæus, is now out of date; we go by the simpler natural system. The lower orders of cryptogamous or flowerless plants—ferns, mosses, and lichens—we need not discuss now. Flowering plants are divided into two great classes—the *exogens* and *endogens*. The first class has a stem formed of *bark, pith* and *wood*; the leaves have netted veins, and the parts of the flowers are mostly in fours or fives. We will take an ordinary dog-rose as a representative exogen, or any tree, in fact. The endogens do not have bark or pith; the stems have the wood collected into bundles or threads; the leaves have parallel instead of netted veins, and the parts of the flowers are generally in threes. Any lily will do as a representative endogen.

Before attempting analysis, the student must, of course, learn the parts of the plant. We all know the five great divisions: root, stem, leaves, flower and fruit. The flower consists of the calyx, or outer cup, formed of sepals; the corolla, formed of the bright-hued petals; the stamens, consisting of filament and anther, the latter containing pollen, and the pistil, formed of ovary, containing embryo seeds, style, and stigma. We should roughly divide flowers into two great classes—simple and compound. Take the rose again, as a representative of simple flowers; each blossom is alone and independent. But what we call a daisy is a compound flower; that yellow center is really a mass of tiny blossoms, surrounded by a leafy basket which serves as calyx to the whole. Each little flower, or floret, is perfect by itself, while in some of the family, such as the daisy, the marginal florets have their corollas lengthened sideways, so as to give the rayed appearance to the flower. These compound flowers form the family of Compositæ.

Try to analyze something you are very familiar with—for example, a rose. You know it is an exogen, and a simple flower. Next thing you notice is that it has both calyx and corolla—a green calyx, which swells as it ripens, until it becomes an ornamental fruit; a row of green sepals around the corolla; five or more bright-hued petals, inserted with the stamens on the edge of a disk within the calyx tube; numerous stamens, and one to many pistils. These are the general characteristics of the large family known as the Rosaceæ, which includes raspberry, strawberry, pear and many other well-known fruits. Examine your rose more closely. You find that the calyx is tubular and urn-shaped the upper part spread into five divisions, making it appear as if those above were the real calyx, and as if they were on the top of a solitary ovary. Make a vertical section through this calyx, and you will find several ovaries concealed in this lower urn-shaped portion, while the pistil which looks like one style with several stigmas at the top, is really a consolidation of many styles; where they struggle through the narrow neck of the calyx. Other members of the rose family show the same style of flower, but the arrangement of fruit and seeds differs so strongly as to destroy all resemblance.

You will notice that the distinguishing traits are not the flower, as we ordinarily term it; that is not the showy petals. The less conspicuous parts of the plant denote its proper place. After deciding whether it is exogen or endogen, simple or compound, you examine closely for peculiarities of form. Take a rose-mallow. It has a green calyx, divided into five segments, which suggests a rose, and the petals offer some similarity. But in the mallow the stamens are united with the base of the petals, and rise in the center of the corolla, forming a tube in which the pistils are enclosed. You may notice this peculiarity, very clearly in the common Rose of Sharon so familiar in gardens. These plants I have mentioned are *polypetalous*; that is, they have both calyx and corolla, the latter of separate petals. The next great class is called *monopetalous*; calyx and corolla are both present, but the latter more or less united into one piece, as in the morning-glory. The third division is termed *apetalous*. These have no corolla and sometimes the calyx also is wanting. Willow catkins are an example.

After deciding to which of these divisions a flower belongs, it is comparatively easy to trace it with the aid of an analytical key. I say comparatively easy, for it requires an amazing power of memory to locate an unfamiliar flower off-hand. Especially is this true of the Compositæ; we should be quite accurate in calling them complicated as well as composite flowers. While the leaves help us to distinguish varieties, they are of comparatively little use in discerning orders or genera; for this we must look at flowers and seed. Much of our work must be done with magnifying-glass, but once begun, it is extremely fascinating, and can be pursued with less expenditure than any other science. COTTAGE MAID.

DOMESTIC NOTES.

THIS year all our fruit has been put up in one way, and that a very easy one. We make no pound-for-pound preserves, but can everything after this fashion. The fruit is peeled, or prepared in any way desired, and then packed into the bottles, with a sprinkling of sugar all the way through. The jars are then filled up with water, and stood in the wash-boiler, with enough cold water to reach three-fourths up the bottles. The bottles are stood on boards to prevent them touching the bottom of the kettle, and the lids are put on, but not fastened. The boiler is stood on the stove and brought to a boil; it is left on for 20 minutes after coming to a boil. This cooks the fruit thoroughly; very soft fruit will do with a little less. When the jars are lifted out, a little boiling water must be poured into them, so as to fill them up, and they must then be sealed immediately. This is a very satisfactory way to do strawberries, peaches and pears.

WE have been greatly tormented with water bugs (croton bugs), a pest that usually appears where the water is laid on. After trying many remedies we at last found the only effectual one in "Concentrated Red Seal Lye," which we scatter in and around the sink. It must be used with caution, for it is terribly caustic, burning away paint if allowed to touch it, nor must it be allowed to touch the hands, but it certainly drives away water bugs and roaches. After letting it lie in the sink over-night, we wash it away with quantities of hot water, thus serving a double purpose, for the lye is excellent for cleaning grease out of the escape pipe of the sink.

NEVER burn or destroy tissue paper which may come in the way of wrappings—it is excellent for polishing windows. Ammonia and water, applied with a sponge, followed by a polish with tissue paper, is our favorite way of window-cleaning. Ammonia should always be used in the water for cleaning glass or silver—it removes grease and gives a good polish. PATTY GARTON.

GOLDEN GRAINS.

THE CHRISTIAN UNION says that the truest hospitality sometimes consists in locking the door, and the truest friendship sometimes involves absolute unresponsiveness to an appeal that ought never to have been made. If you wish to serve your friend, help him to be self-supporting, but do not let him become dependent upon you. Sting him, if necessary, into the consciousness of his own weaknesses, even if it cost his good-will. The surrender of a friendship for such a reason may sometimes be the highest evidence of its purity and nobility.....

THE CONGREGATIONALIST says that it is the honey in the glass, and not the elegance of the glass, that draws the bees; and it is the power of the Gospel in the hearts and lives of its professors, and in the preaching of the pulpit and labors of the pastor, which gives the Word success.....

THEODORE PARKER, when uttering the Lord's Prayer, used to say: "Forgive us our trespasses as we should forgive those who trespass against us!" He also prayed: "Lead us from temptation," instead of "Lead us not into temptation."....

IT is not intellectual work that injures the brain, says the London "Hospital," but emotional excitement. Most men can stand the severest thought and study of which their brains are capable, and be none the worse for it; for neither thought nor study interferes with the recuperative influence of sleep. It is ambition, anxiety, and disappointment, the hopes and fears, the loves and hates, of our lives, that wear out our nervous system and endanger the balance of the brain.....

THE CHRISTIAN UNION says that truth is the foundation of life; it is the principle that gives life its stability. It is the foundation of success for the individual, the community, the State. So great is it in the estimation of earth's finest beings that death is a willing sacrifice for its preservation. So high a place does truth hold in the minds of men that a devotion to it commands respect from those who see errors where the advocate sees truth. For even truth is susceptible to various interpretations. Like all great principles, it is best understood by those whose mental vision is trained to scan the world's horizon. To the mind in the valley, who sees the world through the narrow opening between his native hills, its largest realms are shadowy regions where falsehood dwells.....

THERE is no special grace in truth that reveals itself in brutal statements of facts already too evident. Such remarks cannot lift men above the level of the earth. Nowhere is truth more valuable than in the social circle, where men and women send out an influence searching and far-reaching. But it is truth combined with charity and with love, with an ever-present consciousness of the many-sided-ness of life, and that one mind cannot grasp the inner consciousness of every human being that chance revolution of time throws within its orbit.....

TRUTH is the foundation of life, but not truth alone. To raise a structure fit for the indwelling of the divine, it must couple with it in construction grace, love, self-control, and the intuition that sees in every soul the possibility of suffering, of living, of devotion to a cause. Truth is mighty to uplift or to cast down. To see the truth is the one desire of every man and woman who seeks to reach the divine ideal of the race. But to speak it where only suffering can follow the hearing of it reveals a vulgar mind, living on a low plane spiritually, intellectually, socially. Truth for the upbuilding of man though he be crucified, but silence where its proclaiming means only pain!.....

size of an egg, a table-spoonful of sugar and a little salt. Bake in well-greased, heated gem pans in a hot oven.

LEMON JELLY.

TO ONE package of gelatine add one pint of cold water, the juice of six lemons and the rind of one. Let stand one hour, then add one quart of boiling water and two pounds of lump or granulated sugar. Strain and set aside to harden.

TO PICKLE OYSTERS.

DRAIN the oysters from the liquor and put the liquid over the fire. When boiling put the oysters in—a few at a time—and let remain until the edges curl. Take out and wipe dry with a cloth. When cold put in an earthen or glass dish. Add to the liquid half the quantity of vinegar, boil, skim and strain, add whole cloves and allspice and when cold pour over the oysters. Pickle two days before they are wanted. Serve with thin slices of lemon.

CHOW-CHOW.

ONE peck of green tomatoes chopped fine. Mix a cup of salt thoroughly through the tomatoes and let stand over night. In the morning drain off all of the water. Add eight green and four red peppers chopped fine, a cup of white sugar, any spice you like, cover with vinegar and boil about 20 minutes. Drain and when cool add a pint of grated horse-radish, six minced onions, the white part of two bunches of celery minced, and a cup of mixed mustard. Mix well together, pack in a stone jar, cover with cold vinegar and tie up tightly.

TOMATO CATSUP.

ONE gallon of tomatoes, four table-spoonfuls of salt, three of whole black pepper, three of mustard, half a spoonful of cloves, the same of allspice, a pint of vinegar and three red peppers. Boil three hours, strain pressing through all pulp, bottle hot and cork tightly.

SNOW CAKE.

ONE tumblerful of flour, one-and a-half tumblerful of powdered sugar, whites of 10 eggs, one small tea-spoonful of cream-of-tartar. Beat the whites very light, sift the flour, sugar and cream-of-tartar together, and then stir gradually into the whites. Bake in a round pan—papered—25 or 35 minutes in a cool oven. In 10 minutes after baking, frost it with the white of an egg and three table-spoonfuls of sugar. Cover thickly with grated cocoanut.

MOLASSES LEMON PIE.

ONE cup of sugar, one and a-half cup of molasses, one-half cup of water, two beaten eggs, one large table-spoonful of flour and the grated rind and juice of a large lemon. Mix together. Line tins with a good crust, pour in the mixture with a crust and bake slowly until the mixture thickens and the crust is browned.

IMPERIAL CAKE.

ONE pound of butter, one pound of sugar, one pound of flour, one pound of raisins cut fine, one-half pound of citron cut into thin pieces, 10 eggs, one nutmeg, one wineglassful of fruit juice, one pound of blanched and cut almonds. Bake three hours.

CHILI SAUCE.

ONE dozen good-sized ripe tomatoes peeled, 10 green peppers without seeds, and four onions all chopped together. Then add four cups of sugar, eight tea-spoonfuls of salt, four tea-spoonfuls each of ground pepper, allspice and cloves, and 10 cups of vinegar. Put all together and cook until tender. Then put into fruit cans and screw down the tops.

PUFF PUDDING.

TWO-THIRDS of a cup of butter, a little over a pint of milk, a cup and a-half of flour, six eggs beaten separately. Boil the milk and butter together, pour on the flour, stir well and let stand until cool, add the beaten eggs, bake half an hour in a quick oven and serve with a sauce of butter and sugar.

TIP-TOP PUDDING.

ONE pint of bread crumbs, one quart of milk, yelks of four eggs, one cup of sugar, a piece of butter the size of an egg. Beat all together and bake in a moderate oven. When cool spread the pudding with jelly, then cover with a mixture of sugar and the beaten whites flavored with lemon. Bake a delicate brown.

APPLE CHARLOTTE.

PEEL and quarter some tart apples, boil five minutes, take from the water and chop fine. Have ready some dry bread crumbs, also some seeded raisins and prepared currants. Butter a pudding dish, put a layer of bread crumbs in, then the apples and fruit, and any spice liked, sugar and bits of butter. Thus alternate until the dish is full. Bread crumbs and bits of butter should be the last layer. Pour over the water that the apples were boiled in. Bake three-quarters of an hour. Serve with hard or liquid sauce.

CHOCOLATE MIXTURE TO PUT BETWEEN LAYERS OF CAKE.

BOIL one-half cup of sugar and one-half cup of milk together. Then add the beaten yelk of an egg and a cake of sweet chocolate (scraped) or one-half cake of the other.

MOLASSES CAKE.

ONE cup of molasses, two cups of sugar, one cup of butter, four eggs, four cups of flour, one cup of milk, two tea-spoonfuls of soda.

EXCELLENT MINCE PIE FILLING.

Two pounds of boiled beef chopped fine, one pound of suet made fine, five pounds of chopped tart apples, two pounds of raisins, two of currants, two of sugar, one cup of molasses, two oranges, juice and grated peel, two nutmegs, one ounce of cinnamon, one-half ounce of cloves, one-half ounce of mace. Mix and pack into jars and keep in a cold place. Add cider or fruit juice when using.

RUSK.

Two cups of sugar, one-half cup of butter, one cup of milk, one pint of bread sponge, three beaten eggs and flour to make like bread dough. When light make out into small biscuits. Let get light before baking.

CREAM CAKE.

THREE cups of sugar, piece of butter the size of two eggs, four eggs, one cup of milk, two tea-spoonfuls of cream-of-tartar and one of soda, three cups of flour. Bake in two tins.

CREAM FOR CAKE.

ONE pint of milk, two eggs, one cup of sugar, one-half cup of flour. Mix the sugar, eggs and flour together then pour over the milk. Put the dish containing the mixture into another dish containing hot water and stir until it thickens. Flavor to taste. When cold put between the cakes.

SNOW PUDDING.

ONE ounce of Cooper's gelatine, one pint of boiling water, one cup of sugar, juice of three lemons and the whites of three eggs. Beat the gelatine (after it is dissolved and cold) sugar and lemon juice together with an egg beater. Whip the whites of the eggs to a stiff froth, then add to the other ingredients and beat until stiff. Put into a mold to cool. For the soft custard: Take the yelks of the three eggs with one extra egg to one quart of milk. Heat the milk, sweeten to taste and carefully stir in the beaten yelks. Flavor as liked. Keep on the back of the range until the custard thickens. Serve the "snow" in saucers and pour the soft custard (cold) over it.

COCOANUT DROPS.

ONE pound of grated cocoanut, dried a little, one pound of powdered sugar, one-fourth pound of butter, one large handful of flour. Stir the sugar, butter and flour together, then add the cocoanut, make into little balls and dry in a cool oven.

LEMON CAKE.

THREE cups of sugar and one of butter beaten to a cream, then stir in the yelks of five eggs well beaten, dissolve a tea-spoonful of saleratus in a cup of milk, add then the whites of the eggs beaten stiff and sift in four cups of flour as lightly as possible. Last, add the juice and grated rind of a lemon.

COCOANUT CAKE.

ONE pound of sugar, one-half pound of butter, three-quarters of a pound of flour, six eggs to be stirred in without beating, one grated cocoanut, half a tea-spoonful of soda and one of cream-of-tartar. Put the cocoanut in last.

MRS. D. SNEDEKER.

WATER TOAST.

HAVE a shallow pan with one quart of boiling water and one tea-spoonful of salt. Dip each slice of dry toast quickly in the water, do not let it soak for an instant, then pile on a hot platter. Spread evenly with butter, serve very hot.

To use toast as a garnish for poached eggs, cut into large rounds with a cake-cutter before toasting, put one egg on each piece.

For small birds or for asparagus remove the crusts of the bread and cut it into oblong pieces.

For minces or fricassees cut into small squares or diamonds.

For a border cut, after toasting, into inch-and-a-half squares and then into halves diagonally by making triangles. Or cut the toast into long, pointed triangles.

CANNED CORN.

CUT the corn from the cob and for every six quarts of corn use one ounce of tartaric acid. Put the acid into hot water, stir well, then put in the corn and cook it until it is well heated through. If any scum rises remove it. Can while boiling hot. When it is wanted for the table it should be washed in three waters and put over the fire in cold water; when sufficiently cooked pour off the water and dress the corn with cream or butter and a tea-spoonful of sugar to each pint of corn.

A BAKED BIRD.

TO DRESS the bird, split it carefully down the back and the bird can be cleaned so perfectly, with care, that it need not be washed. Lay it in a pan with a little water with the breast down and allow it to simmer but not to boil for 15 minutes. Before putting the bird in the oven add a little salt to the water in the pan. Do not put salt on the bird, but sprinkle it with salt water. Keep the surface of the bird moist. Let the oven be very hot when it goes in and bake for 15 minutes.

CHICKEN CROQUETTES.

BOIL a chicken in water with a little salt and half a cup of rice added; save the stock, chop the chicken up fine. Take one table-spoonful of butter, one table-spoonful of flour, melt the butter, add the flour and rub it smooth. Add one table-spoonful of rich cream and one-half pint of stock; cook it until as thick as cream, stirring constantly. Season the chopped chicken with a salt-spoonful of grated nutmeg, a little Cayenne pepper and a little salt. Add to it a table-spoonful of the rice that was boiled with the chicken and the yelks of three eggs; mix this, and the prepared cream thoroughly together. Heat the mixture to the boiling point, add a little chopped parsley, turn into molds and when cold remove and dust with cracker crumbs, fry in a pan of fat as for doughnuts.

A. B.

News of the Week.

HOME NEWS.

SATURDAY, September 14, 1889.

EVEN the "Oldest Inhabitant" doesn't remember anything like the violence, duration and destruction of the cyclonic storm that has ravaged the Atlantic coast from Maine to North Carolina for most of the week. During the fine weather at the close of last week several monstrous waves swept in on the watering-places along the Long Island and New Jersey coast, endangering the lives of the bathers and seashore loungers and doing considerable damage to exposed property. At first these were attributed to tidal action, but, later, to a hurricane far out on the Atlantic. Monday the papers thought the ragged rim or the tail of a north-moving cyclone had struck the coast, and since then they have been sure that from Virginia to Rhode Island it has been well within its whirling border. Since Tuesday heavy rains have fallen continuously and the wind has varied between a gale of 23 and a hurricane of 64 miles an hour. It has been invariably from the east to the northeast, and has piled the Atlantic bodily to an unprecedented hight on the coast, besides sending huge waves still further on the land. Even the mild winds of little Lake Erie often bank the waters four feet above their usual hight at Buffalo, and the wind in the narrow pond of Lake Michigan piled the waters eight feet above their usual level along the Chicago front on December 4, 1885. What wonder therefore that a raging cyclone on the broad Atlantic should drive the waters to a still greater hight on the coast. The aggregate amount of damage done on land must be enormous, though as yet nothing approximating a correct estimate can be formed. The New Jersey shores have borne the brunt of the tempest. All the sea-coast watering-places from the mouth of the Delaware to Sandy Hook are scenes of disaster and ruin. Countless buildings have been demolished by the waves and bodily swept away, and hundreds of others have been partly wrecked and undermined. The shore is strewn with wreckage. Atlantic City has been surrounded with water and its 15,000 inhabitants and 10,000 belated visitors have suffered severely from fright and exposure. Between Long Branch and Sea Bright every cottage has been destroyed. Beach Harbor has been entirely cut off and Ocean City, Maryland, has been submerged and its inhabitants rescued with difficulty. Coney Island, Long Beach, Rockaway, and other summer resorts on the Long Island coast have suffered immensely. Besides the temporary injury done by old ocean, it has made disastrous permanent encroachments on the land. For centuries the waves have been steadily eating up the coast from Cape Fear to Montauk Point. Scientists place the average loss along the whole coast at 12 feet a year, and in many places the ravages of the present tempest are likely to exceed those of ordinary storms during 10 years. The losses of vessels and human lives must be apalling. Over 50 vessels are ashore at the mouth of the Delaware, and numerous other wrecks dot the beach from Virginia to Rhode Island. All in all, the eastern fringe of the Great Republic has suffered during the week in a way that will be remembered for years. The September tempest and rain of this week will be as memorable as the March tempest and snow of the "Blizzard Week" over a year ago.....
According to the jubilantly sanguine prosecuting attorney in the Cronin murder case in Chicago, nothing now can delay the hanging of the prisoners but the selection of a jury. A week's efforts to secure 12, however, have failed to secure one. English, Irish, German and Swedish nationalities are objected to by one side or the other in this order; so are Presbyterian, Catholic, Episcopal, Methodist and Baptist creeds; while all who have formed an opinion on the matter are at once ruled aside. It may be possible, but it is sure to be difficult, to obtain 12 good men and true able to hear, talk and see, who have not formed some sort of an opinion in the case. The present absurd manner of selecting a jury, if not the jury system itself, should be abolished.
.....The United States are cursed with one lawyer to every 900 of the population..
.....The National Women's Temperance Union will hold its annual Convention in Chicago on November 8.....
In the race trouble in Le Flore County, Miss., 100 more colored fugitives are reported to have been shot to death, and a body of white regulators are still on the tracks of the surviving malcontents. No white casualties are mentioned. There and elsewhere in the South it is madness for negro discontent to take to threats or arms. White men have all the means of speedy communication and transportation at their command and are always armed and ready to converge ruthlessly from all points at the first announcement of a "nigger 'ruction" at any place. All such dangers to the social, economic and political *regime* must be stamped out at the start, and the punishment must be always "exemplary." Time enough to inquire into its justice—if at all—after it has been inflicted.....
The Hon. Samuel Sullivan Cox, better known as "Sunset Cox" member of Congress from one of the districts of this city, died at his home here last Tuesday night at the age of 65. A genial humorist, a brilliant essayist, a successful author, an able and incorruptible statesman, with friends everywhere and an enemy nowhere, he has left a record of a bright, useful and unstained career, and a host of mourners in all ranks and conditions of life and in every section of the country.....There's a good deal of quiet talk among the great coal barons about the formation of a gigantic Coal Trust..... ..It is now reported on "excellent authority" that barrel-boatman Graham did not really "shoot Niagara." 'Tis all a fake, 'tis said. Bridge-jumper Steve Brodie, rum-mill-keeper of this city, also claims to have done it "on the quiet," in a rubber suit the other day; but his modest claim is denounced as an impudent fraud.....
The forced resignation of Corporal Tanner, Commissioner of Pensions, tendered to the President, after a world of pressure, at one o'clock Wednesday night, was accepted next day. The differences existing between the Commissioner and his superior officer, Secretary Noble, as to the policy to be pursued in the Pension Office, were insurmountable, and so the subordinate was "persuaded" to resign to prevent the other from doing so. Probably another office fully as lucrative, if not more so, though of less influence, will be found for him. Following an antediluvian practice, the conductors of all the opposition papers are now jumping on the prostrate form of the legless veteran.....The entire plant of Dick & Meyer's Sugar Refinery, in Brooklyn, was cremated the other day, causing the heaviest loss ever sustained by fire in the City of Churches. Loss on buildings and machinery, $1,500,000, and on stock, $500,000: total of $2,000,000.....The Western Stone Company, a building-stone "combine" embracing most of those largely interested in the business in the West, was incorporated at Chicago, under the laws of Illinois, the other day "to reduce expenses and put the business on a paying basis."
The meanest of all "combines"—that of the brick-makers and dealers at and about fire-swept Seattle, Washington Territory. A city ordinance provides that bricks or stones must supersede wood in the construction of houses within certain limits, and an execrable "combine" has been formed to double the price of bricks, thus handicapping, hampering and delaying the rebuilding of the burnt district.....
In his will, dated April 23, 1790, Benjamin Franklin left $5,000 to be used in such a way that after the lapse of a century the principal and interest should amount to a sum large enough to make a valuable public improvement. In 1816 John Scott added $4,000 to this sum. The fund now, amounts to about $110,000 and Philadelphia is about to erect a fine public bath with $100,000 of it, letting the other $10,000 accumulate for another century.....The Detroit City Council are accused of having made fortunes by levying a 10-per-cent. assessment on all persons awarded contracts by the city. The second Grand Jury in 17 years is investigating the matter. Three of the boodlers are reported ready to squeal.....Tremendous explosions of gas and furious activity of geysers in the Yellowstone Park, Wednesday, attributed by scientists to the great atmospheric disturbances attending the severe storm raging at the time along the Atlantic coast and elswhere.....
The Democrats at last are "getting together" right merrily. Kentucky, Ohio, Pennsylvania, and New Jersey have one after the other, strongly affirmed the Tariff Reform and Tax Reduction platform of 1888.....Last Monday California celebrated the 39th anniversary of her admittance into the Union shortly after her acquisition from Mexico. With a marvelous capacity for the production of gold, silver, quicksilver, big trees, grains, fruits and millionaires, no State in the Union is blessed with fairer opportunities or richer possibilities.....During the past week Baltimore has been having a glorious time of it celebrating, by a six-day festivity, the 75th anniversary of the defense of the city in 1814, during the second war with Great Britain. The President and most of his Cabinet were present on Monday, and there have been proud parades, fine feasting, and gala goings-on generally. The Star-Spangled Banner which waved on Fort McHenry and which inspired Key with the words of the immortal song during the British bombardment of the place on September 9, 1814, was considered too frail and precious by its owner, Mr. Appleton, of this city, to be lent for display on this occasion.....
John L. Sullivan announces that after his projected money-making circuit and his possible chain-gang experience in Mississippi, he will seek to "slug" his way into Congress from some Bostonian district....
.....The Douglass Axe Manufacturing Company of Boston, after a successful career of 50 years, has been bankrupted by the dishonesty of its treasurer, Denison D. Dana, who entered its services as a boy. He has a wife and six children, moved in the "best society," was a deacon in the Congregational Church, a Sunday-school teacher as well as a liberal contributor to charities and a model of all the graces and virtues, except that for years he had been a steady embezzler of the company's funds, his total stealings amounting to over $500,000. He has disappeared with a 25-year-old son and once more "sassiety" is shocked at the downfall of one of its "pets".....
Ex-Governor Henry C. Warmouth, owner of the finest sugar plantation in the Union, has been appointed Collector of Customs at New Orleans.....Owing to injuries during the Johnstown flood the Pennsylvania Canal has been abandoned, and straightway the coal barons raised the price of coal along the line of that water-way from $2.50 to $5 per ton.....
After a session of three months and an investigation of 3,500 contested votes, a Legislative Committee in W. Va., has decided that Judge Flemming, the Democratic candidate for Governor, had a majority of 214 over General Goff, his Republican competitor.....When Quaker Johns Hopkins founded the Baltimore University that bears his name, having full confidence in the honesty and ability of his protege, Robert Garrett, he made him president of the Baltimore and Ohio Railroad in which he had a paramount influence, and invested the capital of the university in the stocks of the road. Garrett died, leaving many millions to his children, and a badly hampered railroad to the public. His crazy son's mismanagement ruined the road so that it is dividend-paying no longer, and the university would have had to close were it not that liberal friends have come to its aid, temporarily at any rate. The salaries of the professors have been necessarily reduced, however, and makeshift retrenchments are the "order of the day." The Garretts are still enormously wealthy, however .....
Tuesday, September 10, while the people at Baltimore were vociferously commemorating the 75th anniversary of bombardment of Fort Mc Henry and the Battle of North Point, the people at Put-in-Bay, Ohio, were quietly celebrating the 76th anniversary of Perry's famous victory in the Battle of Lake Erie—one of the most notable events of the war of 1812-14.....The bustle has gone so largely out of fashion that Taylor's bustle factory at Bridgeport, Conn., where 600 girls were employed, has indefinitely shut down.....
The agitation for separate schools for Protestants and Catholics, which began in Manitoba, is spreading like wild-fire through Canada, and is likely to cause lively work during the next season of Parliament. The Ontario Government Commission of inquiry into the French schools of the province, objects to many of the text-books as unauthorized and containing Catholic teachings, and in some cases inimical to the Mother Country. It also objects to religious pictures, crucifixes, statuettes and images of saints and even altars in some of the schools. It merely recommends the gradual abolition of existing abuses and the steady conversion of the French into English schools .....

Every Reason for Confidence.

Below we give short extracts from the letters of patients, which contain some hearty testimony.

PROSPECT, CONN., July 2, 1888.
It is to Compound Oxygen, under God's blessing, that I owe my life.
MRS. GEO. SPRAGUE.

No. 4 Third St., E. ALBANY, N. Y., June 14, 1888.
If you want a warm recommendation from one who feels that Compound Oxygen has saved him from the grave, it will be given with the greatest pleasure.
R. S. STEVENS.

PEPPERWOOD, HUMBOLDT CO., CAL., May 28, 1888.
I consider Compound Oxygen a physician in itself. MRS. L. E. SPAULDING.

We publish a brochure regarding the effect of Compound Oxygen on invalids suffering from consumption, asthma, bronchitis, dyspepsia, catarrh, hay fever, headache, debility, rheumatism, neuralgia; all chronic and nervous disorders. It will be sent free of charge to any one addressing DRS. STARKEY & PALEN, 1529 Arch St., Philadelphia, Pa.; 120 Sutter Street, San Francisco, Cal.—*Adv.*

FOREIGN NEWS.

SATURDAY, September 14, 1889.

THE great London strike, which has now lasted six weeks, is likely soon to be settled. Many more of the warfingers have yielded and thousands of the men have gone to work. The dock directors still hold out; but are willing to compromise. They say that for years the property has been paying no interest on the investment, and that compliance with the men's demands would entail an extra expense of $750,000 a year, which would be equal to a capitalized addition of $25,000,000 to the stock. They have always found fat jobs for their friends, however, and money for their own large salaries, besides making fortunes by speculating with the stock in the money market. Like many of the railroad magnates in this country, they have been mismanaging the vast property for their own advantage to the loss of the ordinary stock-holders, and now they want the government to pay the original cost of construction for it, thus making a big thing out of their own maladministration. They are willing to yield to the men's demands after November 1, provided they go to work at once; but the men refuse. The difference would be $50,000, and this sum is being raised by public subscription. All classes in the United Kingdom have generously contributed to the support of the strikers, and liberal sums have been sent from other places, especially from Australia. Workmen here have been liberal with sympathy and sentiment; but the strikers prefer money and meals.....
The other day a tremendous explosion and conflagration terrified the old city of Antwerp, Belgium. A huge cartridge factory and a number of petroleum sheds stood close together within the city limits not far from the river Scheldt, full of shipping. Hundreds of barrels of petroleum were stored in the latter, and about 35,000,000 cartridges, besides a great deal of powder, in the former. A mighty rush of flames from the sheds and a terrible explosion of powder in the factory occurred apparently simultaneously. The flames spread rapidly, and the explosions were deadly and continuous. Vast numbers of the cartridges were buried, and as the blazing oil made its way into the factory it penetrated the ground and caused fresh explosions. The disaster lasted several days and nights, causing a loss of about 35,000,000 francs. Troops surrounded the scene and local firemen, helped by those from Brussels, 45 miles away, and others, worked indefatigably. The shipping was saved by a high wall and hard labor, and none of the time-honored public buildings were damaged; but 135 persons were killed; 21 are missing, 100 were injured seriously and 200 slightly. The government is prosecuting the owner of the factory for "homicide by imprudence;" but he claims that the fire broke out in the petroleum sheds first and thence spread to his buildings.....
Charles III, Sovereign Prince of Monaco, in Italy, with a couple of dozen other titles, died Wednesday at the age of 72. The Grimaldi dynasty to which he belonged, is the oldest reigning family in Europe, having ruled in Monaco since the 10th century. Monaco, whose capital is Monte Carlo, consists of a small peninsula jutting into the Mediterranean, having an area of about six square miles, and a population of about 5,000. On the land side it is bounded by the French department of Alpes-Maritimes. The dead king was blind for most of his life. He had an army of 72 men with as many officers as the Opera-bouffe army of the Duchess of Gorolstein. Since 1865 he has drawn a large yearly revenue from his share in the gambling hell which has made his little principality notorious—the largest and most splendid in the world. Since '69 all taxes have been abolished, all outlays being paid out of the Prince's share in the profits of the great casino. The old man's son Prince Albert, aged 41, succeeds him...
.....Henry M. Stanley is reported to be making his way to Mombassa, somewhat north of Zanzibar, on the east coast of Africa, after conquering all the tribes between the upper Nile and the coast, and establishing among them the authority of the British East Africa Company.....
This company paid nearly all the expenses of his Emin Bey Relief Expedition, and no doubt he engaged to work in its interests. It is trying to do for East Africa what the old East India Company did for Hindostan—appropriate it, and make money out of it. The petty Sultan of Zanzibar the other day made over to it about 700 miles along the African coast, claimed by him and in course of appropriation by the Germans. This company now owns over 1,000 miles of the eastern coast and the land stretching back of it indefinitely. The Germans claim about 600 miles of coast further south, and then come the Portuguese claiming about 1,000 miles, and then again the English to the Cape of Good Hope. There is a bitter rivalry between the Germans and English, but Bismarck says the whole German interests in Africa are not worth the loss of England's cordial friendship. Africa is now the great prize grabbed at by all colonizing Europe.....
Several cholera cases are reported in Athens .....It is proposed to connect Glasgow and Edinburg by a canal at a cost of $35,000,000.....

AGRICULTURAL NEWS.

SATURDAY, September 14, 1889.

THE SENATE COMMITTEE has been investigating the dressed-beef question at Kansas City during the week. The testimony of some of the witnesses makes some very interesting reading. Ex-Governor Glick testified first. He had been in the cattle-raising business for 30 years, during which the prices of cattle had fallen 30 to 40 per cent. He said the cause for this was the establishment in Kansas City of a great packing interest which had developed, first, a great competition among the sellers of cattle, and afterward a combination among packers which was so powerful that members could buy cattle at their own prices. The witness had shipped cattle to Kansas City and placed them on the market at the market price. The packers' buyers protested that the price was too high, and said that if he did not want to sell at their price, he could reship them to Chicago. He did this several times, and found each time that the Armour-Morris-Swift combination controlled that end of the route too. He was forced to sell at their price in the end. The witness asserted that the effect of the depreciation in prices had been to drive many of the cattle raisers of Kansas out of business altogether. The packers also controlled rates on the railroads to a certain extent, and had nearly ruined the butchers' business of Atchison. They would have done so altogether had not the latter city passed and enforced a city ordinance requiring the inspection of beef on the hoof. Before this went into effect the packer could buy his cattle in Atchison, ship them to Kansas City, work them into dressed beef, reship this to Atchison, and sell it cheaper than the local butchers could sell their home-slaughtered beef. The inspection ordinance had remedied this. An Atchison butcher corroborated this testimony. Ex-Governor Glick stated that there were no sanitary regulations at the Kansas City stock-yards, and that the stockmen of Kansas expected Congress to take the matter of Texas fever in hand. J. J. Roe, a stock-feeder of Saline County said that prices of cattle had depreciated three to four dollars per cwt. within the past four or five years, on account of lack of competition due to a combination between a select few of the packers who determine the price to be paid for cattle. He had taken a train-load of cattle to Chicago, received a bid for them in the morning, which he thought was too low and which he refused to take, and could not get another offer. He was forced to sell them in the evening at 15 cents per cwt. less than he was offered in the morning. There was no competition. The substance of the above testimony was given by a number of other stockmen. One witness said there was no use in taking their cattle to other markets as Chicago controlled them all, and that the combination controls the shipping facilities so that they cannot be sent to foreign markets. The witnesses agreed that unless something was done, the cattle business was doomed. One witness said that prices to the consumer had been the same as now as long as he could remember. A scalper, testified as to the manner in which the combination had forced him to stop buying cattle except on a small scale. A member of a packing firm was sworn, but it was almost impossible to get any information from him. He asserted that the dressed-beef business was going to the dogs, that there was too much competition, and that none of the packers was making any money. They stay in the business through "pride and the hope of better times." The witness was forced to admit that his customers had received threatening letters from one of the packers in the combine. His firm, of course, is not in the combination. S. B. Armour, head of the Armour Packing Company of Kansas City, testified that he had no agreement with the railroads, by which he got lower rates, that he was not a member of any combination, that the territory was not divided up among the packers, that competition was very brisk, but he refused to admit any knowledge of any combination in Chicago. Mr. Armour exhibited a balance-sheet showing that the cattle he had killed during 1887 had yielded him 33.6 cents per head profit. He asserted that the prices of all meats except the choice cuts had decreased. The Committee have so far failed to ascertain where these packers have made their millions, as they are doing business at a loss, or at best at a very small profit. Their stock formerly cost them nearly double present prices, so according to all known mathematical laws, they should have failed long ago.....

Farmers in the vicinity of Mifflintown, Pa., are reported to be making preparations to go into peach-growing on an extensive scale. About seven years ago several farmers planted peach trees quite extensively and were ridiculed for doing so. There are now in a small radius about 200,000 trees, many of them in bearing and the fruit is being shipped by the car-load. It is said to be better fruit than Delaware ever grew in its palmiest days. It is large, nicely shaped, finely flavored, firm in flesh and handsomely blushed, making a valuable and attractive fruit. The land best adapted to the growth of the peach has been considered nearly worthless, and could have been bought for a trifle. It can still be bought for $10 to $20 per acre, and many trees will be planted the coming fall and spring.....

.....November 1, a special orange train will begin running from Jacksonville to the Northern cities making the trip in 72 hours or less.....

Dairy Commissioners Thom and Ives of Minnesota and Wisconsin respectively, have decided to join in a call for a convention of Dairy Commissioners to meet at Cleveland, Ohio, November 6-8, for the purpose of discussing laws against adulteration.....

The New Orleans Cotton Exchange sent a circular letter to the Bremen Cotton Exchange on the subject of cotton bagging for cotton. The latter expressed itself as willing to give the new covering a fair trial, and would be glad to see it adopted if it answers the required purpose of covering and protecting the cotton. The Liverpool Exchange, being interested in jute, disapproves of the cotton bagging.....

A Pennsylvania grand jury brought a presentment against the County Fair Association for permitting gambling on the fair grounds.....A steer that was found to be suffering from tuberculosis was killed in a slaughter-house in this city the other day. The meat inspector sent its carcass to the offal dock.....

Crops & Markets.

SATURDAY, September, 14, 1889.

CONSUL-GENERAL MUELLER of Frankfort-on-the-Main reports that the imposition of a protective tariff has largely decreased the imports of bread-stuffs from the United States. The quality of wheat from other countries is inferior to the American article and it is consequently cheaper. Another factor which operates against the trade in American wheat is the indisposition on the part of German dealers to handle it on account of the constant fluctuations effected by the widespread spirit of speculation in this country. He says that a guaranty of permanent fair prices would surely be rewarded by the reintroduction of American grains to almost every grain market. The wheat fields of Russia and India owe much of their rapid development to a desire to shake off the insecurity attendant upon handling American wheat. Millions of dollars were spent in building railroads and assisting grain dealers in Russia and the East, many of which would have been spared had another spirit prevailed on our grain exchanges. One prominent German dealer says:

"American grain is the best. We like it, want it, and are ready to buy it just as we see our way safely toward getting it at prices affected by the regular laws of supply and demand. So long as it remains the object of speculation we shall keep our eyes on India and toward Russia. Our millers and bakers prefer American grain, generally speaking, to all others. It is for your people to say how soon it shall be used here in larger quantities."

There is food for thought in these statements. There is not an over-production of wheat or other grains in this or other countries the present season. Left to the natural laws of supply and demand all the available surplus in this country would find an outlet at satisfactory prices. With the horde of sharks and leeches who, under the guise of legitimate dealing, unsettle the business of the whole nation, and thrive and fatten on the ruin of others, it is impossible accurately to foretell prospective prices. The common gambler is an outlaw who is liable at any time to feel the heavy hand of the law, but these "operators," "brokers," call them what you will, who buy and sell more grain every month than is grown in the whole country in a year are at large. They are non-producers, utterly useless so far as mortal eye can see, yet they thrive, fatten and grow rich while thousands of hard-working, honest, energetic farmers are growing poorer, or at best only holding their own. It is our belief that these vampires have more to do with the proverbial hard times among farmers than any other one cause. What do YOU propose to do about it?

THE WHEAT MARKET is brisk. The stocks of wheat in the elevators have not been so small in years, and the demand for wheat is good. Through the winter wheat belt, reports indicate that large quantities of wheat have been marketed, but the local mills whose stocks both of wheat and flour were nearly exhausted, seem to have absorbed the most of it. Under these conditions prices for the future should be good.

THE severe storm of the past week has injured fruit to some extent, the high winds having blown apples, peaches, pears, etc. from the trees, and in many cases, uprooted the trees themselves. Corn and buckwheat have also been blown down badly, and beans are reported very much injured, to such an extent that holders of old stock are inclined to advance prices. Hundreds of tons of salt hay along the coast have been destroyed by the high water, and some damage has resulted from the same cause in the interior. The weather has had its effect also on the receipts of produce in this city. The supply is adequate for present needs, but the conditions are not favorable for perishable articles.

FRESH FRUITS are plenty such as they are, but choice grades are scarce. Red apples are scarce, and good fruit well packed will sell readily at outside figures. There are very few really good peaches, and those in the market are some of them very poor, and sell very slowly. Fine yellow fruit is wanted. Choice pears sell well, but lower grades are very irregular in price. Plums are firm; some fine Reine Claudes were held as high as $10 per barrel. Cape Cod cranberries have made their appearance and find a fair sale. Muskmelons are scarce and bring good prices.

VEGETABLES of nearly all kinds have advanced as the supply has decreased. Potatoes have advanced, and there is not a very large supply. There is the smallest stock of onions, and the lightest receipts for many months, and prices have advanced materially in consequence. Tomatoes have also been in much lighter supply, as the weather has been unfavorable for their ripening, and prices have advanced. Cabbages and cucumbers are also doing better.

POULTRY is in full supply, and dressed is dull and very low in price, except for turkeys, which are not plenty. Live fowls, turkeys, ducks and geese are in good demand if fat. It will not pay to send poor stock either alive or dressed.

EGGS are advancing steadily in price. There is a good demand for fresh eggs, but the large quantities of held stock tend to keep prices down somewhat.

MAGAZINE REVIEWS.

THE LINCOLN HISTORY in the September Century records the occurrences during what was probably the greatest crisis of the Civil War, the re-nomination and re-election of the President. The Chicago Democratic Convention had declared the war a failure, and demanded that the Government should sue for terms of peace. Greeley and others of the same stripe, who were opposed to Lincoln, were debating the feasibility of making another nomination for President. The signal victories of the Union army and navy during the summer and autumn of 1864 changed all these gloomy forebodings, and assured the overwhelming victory of November 8. During all this exciting canvass, Mr. Lincoln's chief concern was for the safety of the country and the perpetuity of the Republic. Personal success and aggrandizement were not in his mind. In the same magnanimous spirit he received the plaudits and congratulations upon his re-election. "Telegraphing in Battle" describes the methods employed to communicate by wire during the war. In 1861, the value of the military telegraph was first demonstrated on the very route over which Morse's first message was sent. The article describes the principal lines, and gives graphic descriptions and numerous illustrations of the methods of building and repairing, of the perilous adventures and hair-breadth escapes of the devoted men engaged in the hazardous work. The article is by J. Emmet O'Brien, who was an operator in the field. In 1865, in March, he ran a line along with the troops in General Schofield's campaign in North Carolina, and lay for two days in Gum Swamp, transmitting dispatches. The next morning General Cox called at the post and wished "personally to thank the chief operator for the service rendered at the front." He was very much astonished at finding only a boy of 15, muddy and haggard, lying on the ground and too exhausted to care even if the President called. And yet these brave men who contributed so much to the success of our armies, have never received any recognition, except the commendation of all the higher officers. They, their widows or orphans receive no pensions, and they have good reason to feel that Republics are at least forgetful if not ungrateful. Mr. Kennan gives "The History of the Kara Political Prison." John A. Paine gives an article on "The Pharaoh of the Exodus and his Son" in the light of their monuments. Recent discoveries have thrown much light upon the history and reigns of these ancient monarchs, and this article, with its numerous illustrations, is a very interesting one for the student of ancient history. Another installment of "The Old Bascom Place" is given. This serial will be concluded in the next number. "Napoleon in Exile" is an account of that episode as described in unpublished letters by British officers. W. Hamilton Gibson, in "Winged Botanists," tells, in his inimitable style, of the fidelity of various butterflies to single orders of plants, proving themselves, oftentimes, invaluable aids to botanists in cases of doubtful plants. "Masaccio," one of the Italian Old Masters of the 15th Century, is a sketch of a celebrated artist. "An American Artist in Japan" describes and illustrates many curious things in that curious country. "Jufrow Van Steen" is a quaint story of an elopement in Holland in which the daughter of a country merchant was inadvertently assisted to elope with the son of a rich man, instead of being married to his father as had been planned. Of course, our sympathies are with the young couple. George W. Cable has a short story, "Attalie Brouillard." The Century Co., New York.

THE HOME-MAKER for September contains a very sensible editorial on "Going Back to School." There is little anxiety on account of the younglings of the flock, as where the deservedly popular kindergartens are not easily accessible, the mother can teach them at home, unless she is thoroughly conversant, not only with the instructors of the primary school, but also with the companions her children find there. Irreparable mischief may be done to a child's moral tone by evil associates at this impressible age. With older children, also, this is a most important consideration. The intellectual part of their natures should suffer neglect sooner than undergo improvement at the risk of lowering the moral standard. Parents should keep posted in regard to their childrens' studies and progress in their schools, and be able to understand to a certain extent what they are learning. This is good advice, and will apply to the country as well as the city school, in both of which the parents know too little of what is being done. Maria Blunt tells, in "After Antietam," of the devoted service of the Southern women in caring for their wounded soldiers in the face of almost insurmountable obstacles. Estelle Thomson in her very interesting Wonderland series tells of "Oranges in California Groves." The first orchard in that State was planted about 1800, near the old mission in San Gabriel Valley, and no other of any size was planted until 30 years later; while in 1870 a budded orange orchard was not known. A curious industry in connection with orange-growing is the supplying of bridal wreaths and brides' bouquets. Extensive orchards are cultivated exclusively for supplying this demand which is the same summer and winter. A fully grown orange tree will yield about 25 pounds of flowers annually, those from the sweet oranges bringing four cents, and from the bitter ones six cents per pound. "An Old Connecticut Homestead" describes the Smith House at Sharon, in which nine generations of that illustrious family have had their residence. The first of the family came to the State in 1636. "Cheap Living in Cities" deals with different ways of cooking meats, etc. "Creole Cookery" describes divers delectable dishes served in lower Louisiana. "Eastern Housekeeping in the Far West," is an account by Margaret Spencer of her experiences among the far away natives of New Mexico. There are articles about "Household Decoration," "Care of the Toilet," "Art," "Our Baby," "Household Health," "Fashions," "Window Gardening," etc. The Home-maker Company, New York.

CATALOGUES, ETC., RECEIVED.

HAY AND STRAW CROPS.—F. Williams & Co., hay and straw dealers of this city, have issued a hand-book containing estimates as to the amount of hay now in the country. They think there has never before been a time in this country when so much hay was ready to be placed on the market as there is at the present time. There is a scarcity of good grades of hay; in fact, the proportion of the whole amount that can justly be called "prime" has never been smaller. It therefore seems safe to conclude that prime hay will realize strong figures while "clover mixed" and "shipping" will find very slow sale. This is exactly what the R. N.-Y. has repeatedly said. The outlook for straw is given as follows:

"All kinds of straw have been secured in a poor state as a general thing, and prime lots will no doubt bring strong figures, but anything that is stained or dark-colored, will rule low."

Williams & Co. suggest that the following rules for the grading of hay should be observed:

No. 1, OR PRIME HAY—Shall be pure Timothy, properly cured, bright, natural color, sound and well baled.

No. 2, OR GOOD HAY—Shall be Timothy, not more than one-quarter (¼), mixed with "Red-top" and "Blue Grass" properly cured, bright color, sound and well baled.

No. 3, OR MEDIUM HAY—Shall include all Timothy not good enough for No. 2, proportionally mixed with Blue Grass, Red-top and clover, sound and well baled.

CLOVER MIXED HAY—Shall include all hay containing not over two-thirds (⅔) clover and one-third (⅓) Timothy, properly cured, sound and well baled.

SHIPPING HAY—Shall include all hay not good enough for other grades, and may be natural meadow free from wild or bog, and must not contain over one-third (⅓) clover, sound and well baled.

CLOVER HAY—Shall be medium grown, properly cured, good color, sound and well baled.

NO GRADE, OR REJECTED HAY—Shall include all hay badly cured, musty, stained, or in any way unsound.

PEAR BLIGHT AND APPLE POWDERY MILDEW.—Circular No. 8 from the section of Vegetable Pathology, Department of Agriculture, Washington. The papers of late have noted the fact that Prof. Galloway has discovered a sure preventive of the above-named diseases. We presume the authority for this report is found in this circular. Both of the diseases have been described in the RURAL. They are familiar to most nurserymen. The R. N.-Y merely gives the mixtures used for curing the diseases. For pear blight the Bordeaux Mixture was sprayed upon the trees. This mixture was made as follows:

"Six pounds of sulphate of copper were crushed and dissolved in 16 gallons of water; four pounds of fresh lime was then slaked in six gallons of water, using, of course, another vessel for the purpose. When the two solutions had cooled they were poured into a barrel and thoroughly stirred with a wooden paddle. For applying the mixture a Japy pump with Vermorel lance and nozzle was used." The first application was made on June 5 and was followed by four others at intervals of 10 days. The treatment was in all ways satisfactory, the trees retaining their leaves in excellent condition, while some not sprayed were almost ruined by blight.

For the powdery mildew the first preventive tried was a solution of sulphuret of potassium (liver of sulphur). This was not a success, as the solution was not thrown evenly and was too easily washed from the trees by a light rain. It was then decided to use a solution of ammoniacal carbonate of copper. This was prepared as follows:

"To facilitate the work of spraying, three barrels were placed in a road at the east end of the block, the first at the south side, the second in the middle, and the third at the north side. Everything being in readiness, the barrels having previously been filled with water (44 gallons), six ounces of carbonate of copper were weighed out and placed in an ordinary water-pail. A half gallon of ammonia was then slowly added, at the same time a complete mixture was effected by stirring with a wooden paddle. Two minutes' stirring was sufficient to completely dissolve the copper, and the solution, which is of a beautiful blue color, was then poured into the central barrel and mixed with the water by means of a long stick. A moment's stirring and the solution, which was now of a light blue color, was ready for use."

This treatment gave excellent satisfaction. These experiments were tried on a very large scale, hence Dr. Galloway's confidence.

SIDNEY TUTTLE & COMPANY, BLOOMINGTON, ILL.—Wholesale catalogue of trees, plants, shrubs, roses, bulbs etc.

GREEN'S NURSERY COMPANY, ROCHESTER, N. Y.—An illustrated circular of the Wilder Pear. This is an early pear of decided excellence.

HARNESS & BUGGIES.—Catalogue from the Wilbur H. Murray Manufacturing Company, Cincinnati, Ohio. These goods have been very extensively advertised of late and we know that a good many RURAL readers have bought them. No complaints have reached us. We judge therefore that the goods suit and that those who buy them get their money's worth. This is the desired end in all bargains.

JOHNSON & STOKES, PHILADELPHIA, PA.—An illustrated catalogue of seed wheats, grass seed, etc. Several kinds of new wheats are offered. The catalogue should be examined by all wheat growers

Law.

"Every Man is presumed to know the Law. Nine-tenths of all Litigation arises from Ignorance of Law."

RENEWAL OF JUDGMENTS: SEARCH FOR LIENS AGAINST LAND-TITLES; A MORTGAGE AS ADDITIONAL SECURITY TO LAND-TITLE.

Subscriber, Mercer County, N. J.—1. Can judgments in New Jersey be renewed when the 20 years have expired, or are they outlawed? 2. Smith sold Brown a tract of land in 1868 and Brown sold it to Jones in 1884. In making search in the Supreme Court now, is it necessary to make one against Smith, and would not a search against Brown for 15 years, ending with 1884, be sufficient; the search against the present owner Jones, of course being for the 20 years last past? 3. I recently purchased a farm subject to mortgage. The mortgage is quite old and the property has changed hands seven times subject to it. I now wish to pay it off; but I want to keep it alive as it will give me a stronger title. Can I have it assigned to myself, and, if so, could I assign it again at any future time should I wish to raise money?

ANS.—1. Section 7 of the New Jersey Act for the limitation of actions provides that judgments in any court of record may be revived by *scire facias*, or an action of debt may be brought thereon within the 20 years next after the date of such judgment. 2. In the case of the real estate sold by Smith to Brown in 1868, and by Brown to Jones in 1884, a search of the Supreme Court records for judgments which might be a lien upon the property, should, as our friend suggests, be against Jones for the 20 years last past, and against Brown for the 15 years ending with 1884. Such a search would be sufficient to cover every contingency except that in which a judgment may have been rendered in favor of one who was insane or under the age of 20 years, in which case the time during which this disability continued, would not be included in the 20 years. 3. Frequently, as in our correspondent's case, it is an advantage to the purchaser of real estate to keep a mortgage alive as an additional security. Where this is the case, the purchaser is at liberty to have the mortgage assigned to him, and to hold it as a separate title. It may be assigned by him at any future time or dealt with by a satisfaction piece or otherwise like any other mortgage.

LIABILITY FOR INJURIES FROM DEFECTIVE HIGHWAY.

J. K. Mc L., Corinth, Ill.—While hauling logs last spring, one of the logs, owing to the bad condition of the public road, rolled off the wagon and fell on me, nearly killing me. Am I entitled to damages?

ANS.—That depends. A city or town is liable for damages for all injuries occasioned by its neglect to keep the streets, roads or bridges in proper repair, provided ordinary care to avoid injury, was used by the plaintiff; but the person suffering the injury must in no way contribute to it by his own act; for if he knows the road to be dangerous and can conveniently avoid such danger, he must do so. The aggrieved party, if entitled to receive anything, is entitled to receive compensation; 1, for loss of time and labor, the amount of course depending on his capacity for earning money, and the nature, extent and probable duration of his disability; 2, for the expense to which he has been and probably will be subject for care, nursing, and medical attendance; 3, for his physical sufferings; 4, for his mental sufferings, and the pleasures and enjoyments of which he has been and may be naturally deprived. In cases of aggravated wrong, juries are frequently permitted to give what is called exemplary, vindictive or punitive damages; that is, something beyond mere compensation, as a punishment to the wrong-doer.

A TENANT'S RIGHT TO CROPS.

Constant Reader, Bergen County, N. J.—I wish to sow some rye this fall, but I may vacate the farm on the expiration of my lease, in April 1890. Would I be legally entitled to harvest the crop after the expiration of my lease?

ANS.—No. A lease-holding tenant who plants a crop which he knows cannot mature until after the termination of his tenancy will lose the same. A tenant whose estate is of uncertain duration, however, as, for instance, a tenant at will, or from year to year, is entitled to the crops known as *fructus industriales* growing at the time of the termination of his tenancy. The different cereals would be of this class, while clovers, grasses or the fruits of trees would not. Such a tenant or his representative, after the termination of the tenancy, has a right to enter upon the land to cultivate the crop if it is a growing one, and cut and harvest it when fit, and if interfered with in the reasonable exercise of this privilege by the landlord or his representative or if the crop is injured by either, he may recover damages for the same. The person whose tenancy ends at a certain time, however, in accordance with terms of the lease or who by his own act has brought his lease to an end—as by abandoning the premises or failing to perform any stipulated condition—has no such right.

BOUNDARY FENCES.

J. A. S., Plainfield, Wis.—A and B own adjoining farms. A owns land between B's buildings and the public highway, but B owns land running to the highway and is obliged to have a roadway cut on the line between his and A's land. B having a good fence on his side of the road, is he legally obliged to keep in repair one half of the fence on the line between his and A's land on the opposite side of the roadway, said road being open to the highway?

ANS.—Yes. A boundary fence must be on the line; and B's fence is not on the line. Indeed it was obviously built away from the line for B's exclusive benefit and convenience Why should A, solely for B's benefit, be required to go to the expense of protecting his land from trespass, by building the half of the boundary fence which the law requires B to build and keep in good repair? Evidently neither in law nor equity is he obliged to do so. If B should place a gate across his private road where A's half of the boundary fence ends, there would be little danger of the trespass from animals wandering from the highway; but should injury occur on A's land from such trespass, owing to any defect in the gate, or through carelessness in closing it, B would be liable for damages therefor.

T. S., Seneca County, N. Y.—After a long illness, during which he had leased his large farm for a term of years, a man dies leaving a widow and four children. For three years the widow and the children received the net income of the property—one-third to the widow, and one-sixth to each child. On the death of one of the children, who was unmarried, what would be the shares of the widow and each of the children?

ANS.—One-twenty-fourth part of the estate should be added to the share of each of the survivors, giving the mother nine-twenty-fourths, and each of the three living children five-twenty-fourths of the income.

S. M. S., Clermont County, Ohio.—A made a verbal contract with B, in the presence of witnesses, for the lease of B's farm, possession to be taken in the following spring. When the time came, A refused to let B have the farm, and rented it to another. What remedy has A?

ANS.—None whatever. A verbal promise to rent a farm is good, provided there is a partial performance; but where there is no partial performance there is no remedy for a violation of the promise.

L. T., Matoon, Ill.—Where can I get copies of the Game and Fish laws of Illinois and Missouri?

ANS.—"Fur, Fin and Feather," a bimonthly, published at 14 Warren Street, this city, contains a compilation of the Game and Fishing Laws of all the States in the Union.

Farm Economy.

MR. TERRY'S FARM IMPLEMENTS.

SOME weeks ago the R. N.-Y. promised its readers a picture of the tools in use on Mr. Terry's 50-acre farm. This picture will be found below, at Fig. 239. We have been able to secure an excellent reproduction from the photograph sent us by Mr. Terry. It is an excellent picture—one that will cause a good deal of thought and discussion. It is an apt illustration of the wonderful possibilities of photo-engraving. The picture tells more than a book of printed matter ever could tell. The R. N.-Y. is happy to state that it is in position to make use of all the great resources of photo-printing. This picture is but the beginning of a series that will open an entirely new field for agricultural journalism. Mr. Terry describes the picture as follows:

"The picture does not show all the tools I have, but those I have used or shall use this year, and which I would buy again if starting anew. The location is in the road and in one corner of the lawn. Beginning in the road, to the right hand, you see first our big wagon, with three horses attached, and a load of potato boxes on it. This is a view of the rig just as it looked when I returned from the cars last fall, after taking up a load of potatoes. You will notice a folded canvas on the boxes, that will cover the entire wagon to keep off rain or sun; also the umbrella which has sheltered the writer while riding many a month. You will get a little idea of the size of this wagon when I tell you that there are 72 bushel boxes on it (not all I have by any means). There are bolster springs to go on when needed.

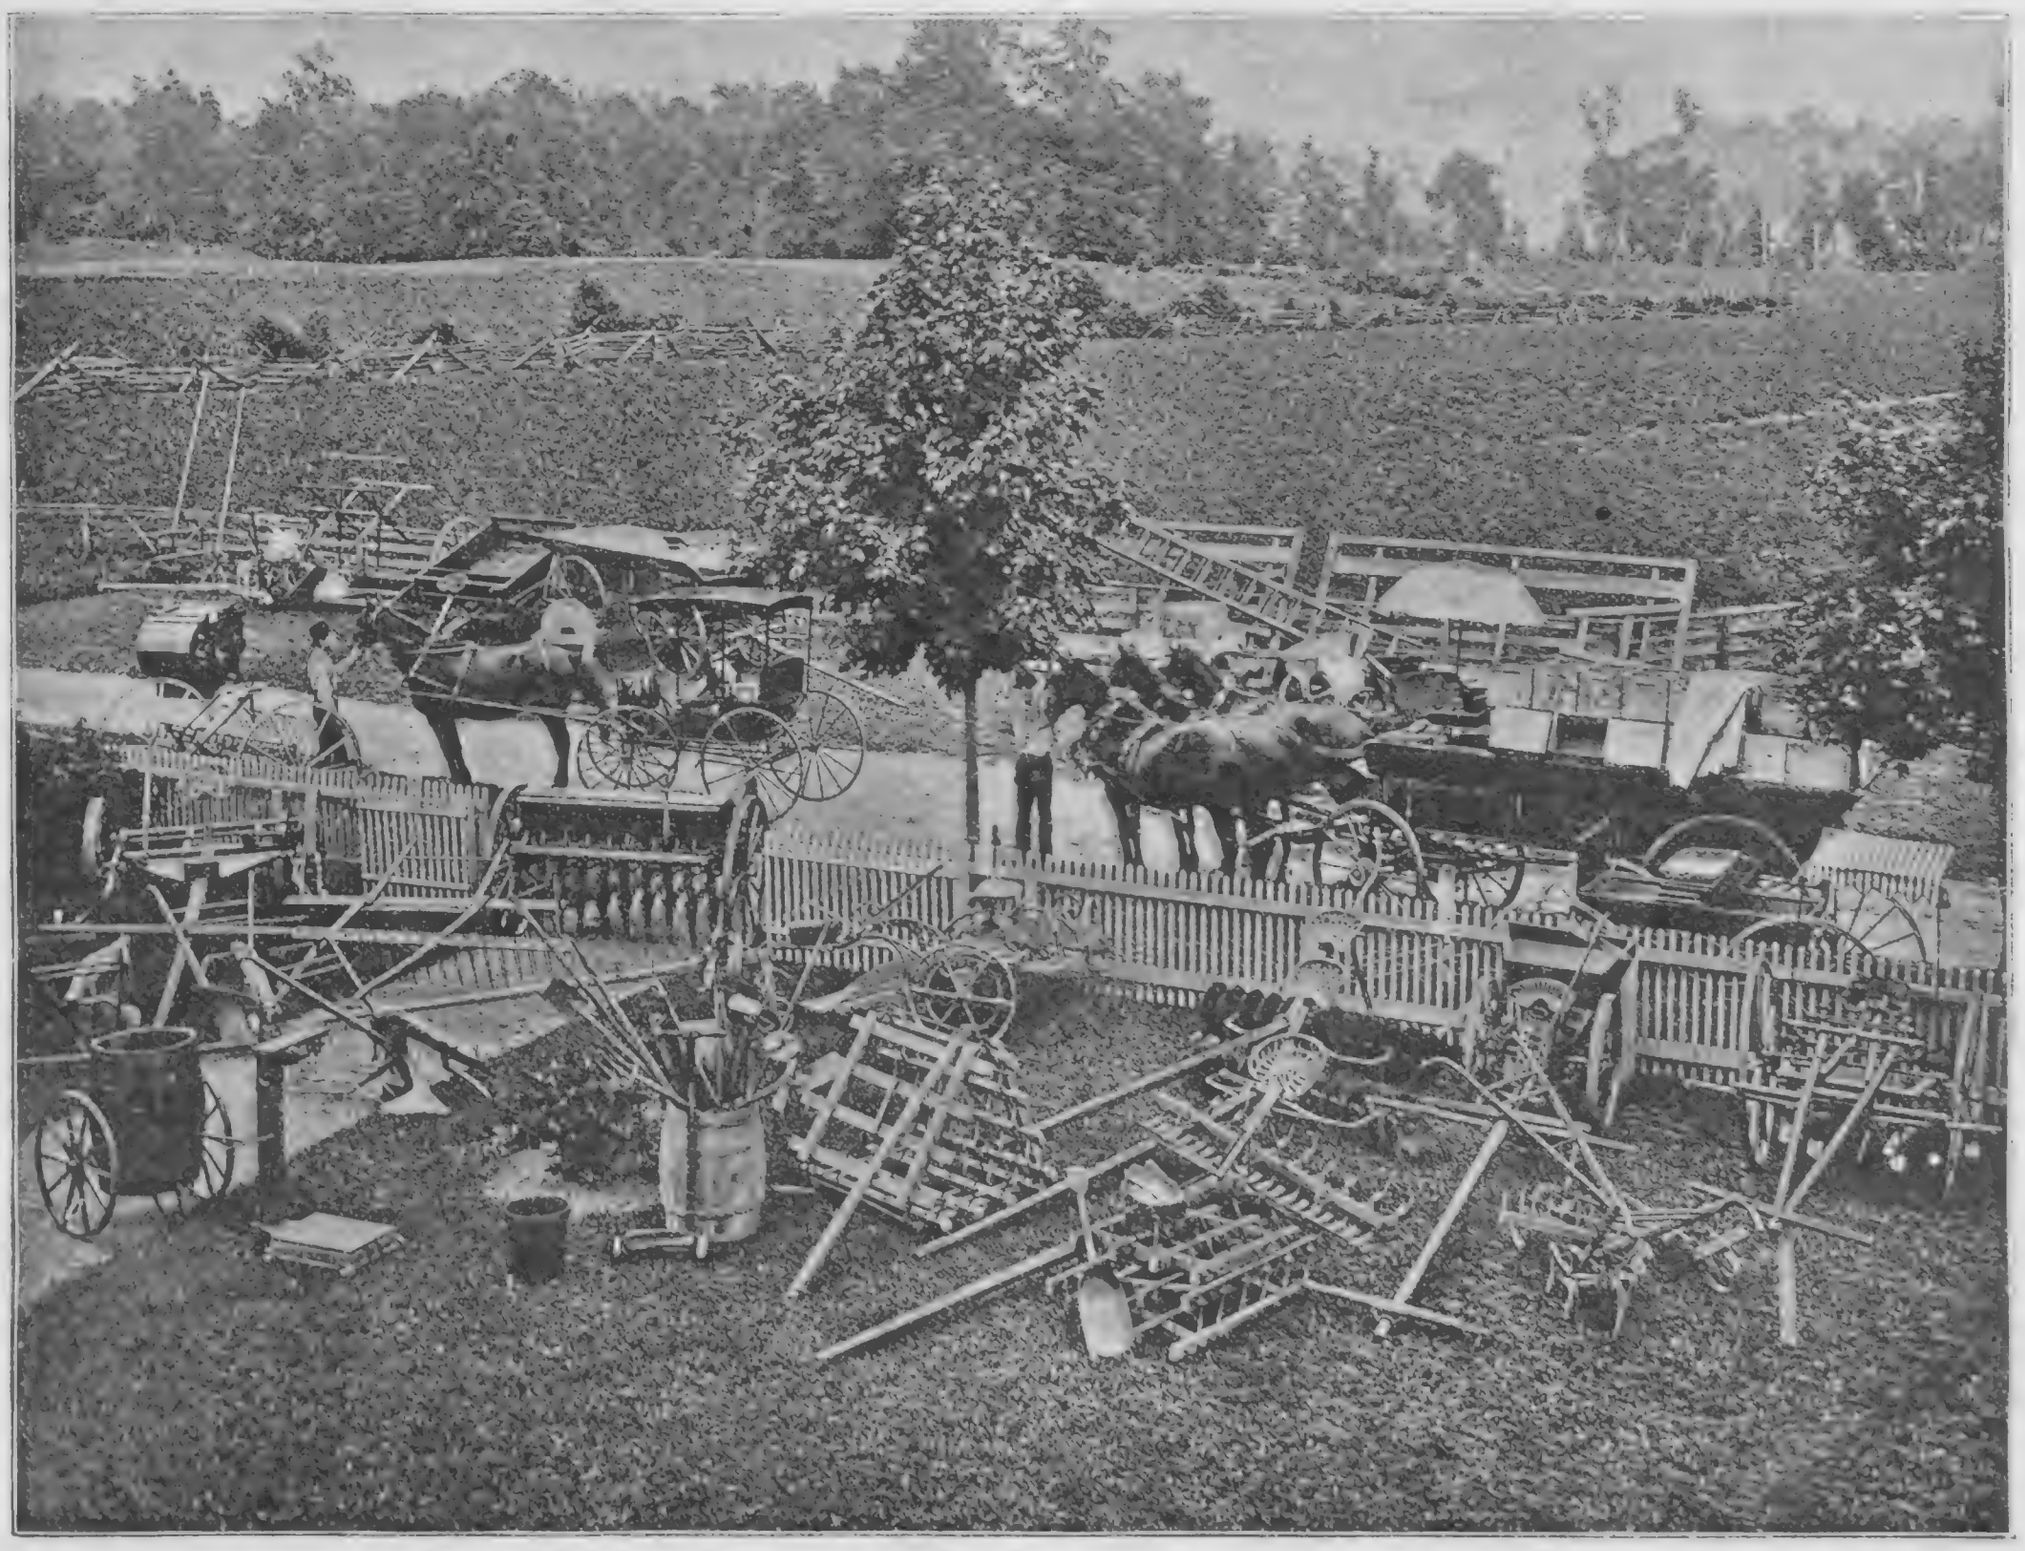
In front of the wagon is the buggy; back of it are two hay-racks, an extension ladder that will open to 35 feet, the wheel-barrow that takes manure out of the stables and the land roller, which is partly hidden. Next come a pleasure carriage, a smaller wagon, a grindstone, the Kemp manure-spreader, which I have used about eight years, the little Buckeye low-down binder, wagon and carriage poles, mill to clean the seed wheat and clover, and a horse-dump rake. I have many a time drawn 66 bushels of potatoes in bulk on the small wagon. The side-boards on both wagons are portable—they can be taken off or put on in a minute, while they make the wagon able to carry a large load without its being very high to load into. They are home-made and have been in quite constant use for many years.

In the gate-way may be seen my Empire drill. This seems to me to distribute the grain more evenly than any other implement I know of, and that is the important point. To the left of the carriage road is our old fast friend, the Eureka mower, and a pair of the largest size Oliver chilled plows. On the walk is Breed's weeder, a very light smoothing harrow, which we used twice this year after the potatoes were up. It cultivated two rows at once and hoed them perfectly at the same time, going over seven acres in five hours—a valuable little tool for clean, mellow soil. In front of it stands a Planet Jr. potato-digger sent here to be tried, which I did not intend to have in the picture, although it may prove worthy of its place. Before it are our scales, a pail from our earth-closet, which I may speak of at another time, and the barrel on wheels that takes the slops away from the kitchen. This latter I told about last year in the RURAL.

There is behind that barrel a pretty little flower bed filled with samples of small tools. In the rear of it stands the best potato-digger on earth, so far as I know. It is the Hoover. It is well made and will do the work perfectly, the only objections being the cost and power required.

Next come tillage tools. In the foreground are two Thomas harrows, next an Acme, followed by a Cutaway and plain disk. On top of one Thomas harrow stands our little Cahoon seed-sower, which has been used 20 years with great satisfaction. By the side of the disk harrow stands an Aspinwall Potato-planter—one of the most perfect tools I have. I have no grain-drill yet that puts in wheat as evenly as this does potatoes. Next comes the new Bicycle cultivator, for narrow rows. It is the only riding cultivator I ever saw that I could do satisfactory work with in the potato field. You see it is up to the times—it has not only a spring seat but a canopy top! In front of the sulky cultivator are two Planet Juniors, with narrow 1¼-inch teeth. On top of one you will notice a little harrow This is a home-made attachment to the cultivator for use in strawberries particularly. The teeth and teeth standards are taken off the cultivator and this attachment is bolted under side. It makes a prime little harrow-toothed cultivator that will not track. It moves the soil close to strawberries without covering any leaves or runners.

The picture of the horses is not fair to them at all. I do not think I would know them. After taking five negatives we gave up getting a fair picture of them with the



GROUP OF TOOLS USED ON T. B. TERRY'S FARM. From a Photograph. Fig. 239.

tools. You will notice the artist had to rub the tails off, mostly, in his negative. We were simply unable to keep four tails still at once in fly time. Those bushes in the fence corners in the back-ground do not belong to me. The winter tools, sleigh, sleds, etc., were not brought out.

You will notice I have two wagons, two hay racks, two plows, two Thomas harrows and two cutting harrows. At first glance this might seem extravagant for such a little farm; but I have two teams, and the ability to rush the work when the conditions are just right is frequently worth more to me than the interest on an extra tool for five years. I have a tool-house 22x56 feet, where these tools are always kept when not in actual use, so that they will last almost indefinitely.

With all this accumulation of tools I am able to grow good crops and do the labor connected therewith quickly and easily. The drudgery of 20 years ago is mostly done away with, particularly as I do not attempt to do half so many things as I used to, but rather a few things more thoroughly well. I ride and plant an acre of potatoes in two hours, all complete, and dig them in the same time. No more hoeing is needed to keep fields clean. I ride and spread a load of manure in two minutes and so on. Young friends must not be discouraged, however, if they cannot afford all these labor-saving devices. It has taken me just 20 years to get all these things together and pay for my farm and put on such buildings as I wanted.

Dairy Husbandry.

Farrow vs. Fresh

SHALL WE BREED DAIRY COWS EVERY YEAR OR ONCE IN TWO YEARS?

THE following discussion was brought out by this letter from a subscriber in Pennsylvania:

"I have a herd of 10 Jersey cows. I make butter and feed my skimmed milk to pigs. I do not care for the calves. Can I get more milk or butter by breeding my cows every year than I can by breeding them once in two years? It is my belief that, all things considered, the latter course will give the best results."

FROM SMITHS, POWELL & LAMB.

OUR belief is that more milk and butter will be obtained when cows have calves once a year, than when they breed only once in two years.

Syracuse, N. Y.

FROM C. M. WINSLOW.

I HAVE never experimented to learn this point, but I have found that where I have been unable to get a cow in calf and she has run many months farrow, I have not got as much from the average of the two years as I have from two years of the same cow when she has calved regularly. She is very apt not to do very much after the first year, and goes dry a long time, or gives but very little milk. The method by which I have received the largest returns from my cows is to have them calve in the fall, feed them well through the winter, etc., then when grass comes they get a new start and are dry in the hot, dry part of the season, when feed is short and butter is low-priced, and they calve again for another winter's work. This correspondent might divide his herd, weigh the milk of the whole and let half the herd calve every year, and the others calve in two years, and test his milk by the "Short method" for butter fat—and he could tell to a certainty just which way was the better.

Brandon, Vermont.

FROM M. H. C. GARDENER.

FOR my purpose of producing a large quantity of milk, I prefer to let a cow go dry at least six weeks once a year, but, unfortunately, some cows—and good ones too—go dry for a longer period. There are a very few farmers in this county who do not keep any bull, but milk a cow for all she is worth; that is, as long as she will give milk in paying quantity, and in the meantime she is fed heavily, so that when she is dried off she is ready for the butcher; but they have a special market for their fat stock; perhaps they run a butcher wagon themselves and so get all the money there is in the beast. But the average farmer could not do this, for the country butcher will give for a fat cow only about half what a new milker is worth, so the loss in changing cows is too great to run a dairy successfully on this plan. It occurs to me, therefore, that the proper way to run an average dairy is to let the cows come in once a year, so that each can get a needed rest by "drying off."

Orange County, N. Y.

FROM C. S. RICE.

A GOOD cow that is well fed, will yield nearly as much milk and butter when allowed to breed but once in two years as under the usual management, producing a calf yearly. Cows giving the same amount the first year will vary greatly in production when farrow. With the common dairy stock of the country, there is no question that yearly breeding is more profitable than the breeding in longer periods. With the improved milk and butter breeds, however, it would require careful and continued experiment to determine the relative profit of a dairy under the different methods of management proposed. From my own observation in a dairy of Holstein-Friesian grades that are persistent milkers, I think that a loss of 10 per cent. would result from the two-year course. A good cow well fed and carefully milked, will continue to yield a profit through 10 months of the year, and need go dry only four or five weeks; that is, during the time when the milk is not fit to be used. The same cow will go dry only a little longer at the end of the second year on the two years' plan; but for a long time the yield of milk will not be large and she will be in fair condition for beef. Yearly breeding and giving milk are normal conditions of the dairy cow. The greatest yield of milk is obtained during the first few months after calving and the yearly return of this period of maximum flow tends to the full development of milk production. On the other hand, with the two years' system the longer time of comparative idleness towards the close of the term and consequent tendency to flesh, are not favorable to such development. It is only a matter of opinion, but I am quite sure that continued restriction of breeding under the proposed two years' system will result in much less profit from the dairy than with the usual management.

Lewis County, N. Y.

FROM DAVID CARLL.

I HAVE kept 20 Jersey cows for butter for the past 10 years and find it best to have them "come in" every year. I like to have one or two calves in each month of the year. I think we can churn more quickly, and make better butter by having fresh cows each month. I have no doubt that more milk and butter can be got from a cow that comes in in the fall; but as we have a greater demand for butter in the summer, I prefer to have them calve at different times in the year. A good Jersey cow will milk within a month of calving, and I am quite sure will give more by calving each year than by going two years. The heifer calves should be worth a good deal more.

Suffolk County, L. I.

FROM J. MCLAIN SMITH.

I HAVE had no experience in this matter at all. The calf, with me, is so important that I breed my cows as soon as they come in, and usually the calves follow each other within the year. Whether a cow would give more milk, or make more butter, bred once in two years, I should say would depend on the cow. Some cows, if farrow, will milk for a long time nearly up to their maximum; others will go dry, or drop off to a very small yield, whether in calf or not.

Dayton, Ohio.

FROM H. S. WEEKS.

I AM unable to see how this correspondent can expect to get as much milk and butter from his cows by breeding them but once in two years as he would if they came in fresh every year. He says his cows are Jerseys, which would doubtless be quite persistent milkers throughout the two years; but, judging from my own experience, the aggregate amount of milk and butter will be considerably larger if they breed every year. The flow of milk from fresh cows for at least half the second year will be, as a rule, double what it would be if they were farrow, and there need necessarily be only a short interval during which no milk is given if they are bred yearly. Many of my own Jerseys milk the year round in spite of all efforts to dry them off, and the average time that the herd go dry does not exceed one month. He says he does not care for the calves; but it seems to me he is thus losing quite a respectable sum from the yearly income that might be derived from this source, for I find the demand for young Jersey stock very urgent, and if his cows are registered, the calves of both sexes ought to count materially in making his decision whether to breed oftener than once in two years.

Oconomowoc, Wis.

FROM F. D. DOUGLAS.

THE production and development of young, in the Animal Kingdom, is one of the incomprehensible mysteries of creative power. While we can not explain or indeed understand the origin of animal life, we may comprehend the laws by which its development is governed. In mammals the secretions which we call milk, are provided by Nature for the development of the young until they become self-sustaining, when the object of the secretions is accomplished, and they are naturally discontinued. While the laws which govern these processes are unchangeable, results may be greatly modified by artificial means, or, in other words, by changing the conditions under which they operate. Cows running wild upon the plains, dry off much sooner than those found in our best dairies. The cow, with us, is, to a great extent, an artificial animal. By the supply of properly constituted rations, good care, and breeding, her milk-producing powers have been developed; she produces much more milk at the outset, and her flow is much longer continued, than when in an undomesticated state, yet there is a limit to this, where Nature requires a return to original conditions, and there must be a reproduction of offspring to insure the best aggregate yield of milk.

Practically I find that where cows are kept in milk over 11 or 12 months, they are quite sure to convert more of their food into flesh, and less into milk than when bred to come in annually. The best of cows will often thus take on flesh and become dry before the close of the second year, though fed on the best milk-producing rations. A good dairy cow, with proper food and care, will continue to yield a large amount of milk during nearly the entire year when in calf every 12 months. Without these conditions of food and care, she will dry off as when in her natural state, or if, by reason of a superior milking development, there should chance to be a continued flow, it would be at the cost of debility in the mother and a weak and imperfect development in the calf. Under favorable treatment both the mother and progeny may be healthy and strong, though the former may continue to give a good flow of milk for 11 months out of the 12, and yield a much larger aggregate amount of milk in two years than when in calf but once during the time. By allowing our cows to remain in milk so long after calving, we get too far from those natural conditions which underlie a large and healthy production of milk, which maternity alone supplies.

Whiting, Vermont.

FROM A. P. ROWE.

I would by all means breed cows annually, and arrange so that they will drop their calves in late fall. In this way one would be able to make much more butter during the winter, when it always commands the best price, and when the cows are turned out on grass in the spring, or soiled, their yield of milk would increase very much, and they could be milked until within a few weeks of calving again in the fall. In this way, the receipts for the butter sold would be at least one-third more than if the cows were bred only "once in two years."

Fredericksburg, Va.

Here is a note about hens with clipped wings:

"White Leghorns with clipped wings are apt at moulting to droop and appear sick. The quills in the clipped wing are not shed as quickly as those in the other wing, and require to be gently extracted. At least this is the observation of a JERSEY-WOMAN."

Have any of our readers noticed this?

Rural Topics.

Linseed Lightens Labor.

WATCH WAGON WHEELS AND SAVE BY SOAKING.

"There has been much said about the economy of soaking wagon wheels in linseed oil. Does it really pay? What do farmers who have tried it say?

FROM A. L. CROSBY.

I have not used linseed oil for the purpose indicated by the RURAL, but have used crude petroleum and think it pays well. I have just finished oiling not only the rims, but the entire woodwork of a two-horse farm wagon. It is astonishing how much oil the rims will absorb in a hot, dry time. As fast as the brush is drawn over the surface the oil disappears, and when a piece of sappy wood is met with it takes up oil like a sponge. I think linseed oil better than petroleum, but the expense is too great to use it as freely as it ought to be used. It is no use advising farmers to pay 60 or 70 cents per gallon for linseed oil and soak the woodwork of their wagons and implements with it; when they see the oil going into the wood so rapidly they will stay their hands and say: "Behold, that is quite enough," long before the wood is filled. You can't do a first-class job when you are all the time trying to save in the materials: if you are repairing a fence and put in one nail where two are needed or try to make one rail serve for two; one load of manure instead of three, or a pint of oil where two quarts are required. If a farmer buy a barrel of crude petroleum and use it freely on his implements he will save its cost every year—provided he is what is called an "average" farmer whose tool shed is coextensive with his farm.

Crude petroleum is easily applied and is cheap; mine cost 8½ cents per gallon—and it will penetrate wood deeper than the heavier linseed oil; its uses on the farm are almost numberless. It can be used in the hen house to kill lice; on pigs and other animals for the same purpose; on dogs to kill fleas; on plow moldbards to keep them from rusting; on gate hinges to prevent wear and squeaking; on roofs to prevent decay; on siding to precede and save paint and on any kind of exposed wood-work. It is always ready for use and its cheapness will cause it to be used where a more expensive oil or a paint would not be. I believe if the rims of wagon wheels are kept filled with crude petroleum they will never decay and the tires will not need setting nearly so often.

Catonsville, Md.

FROM H. A. WHITTEMORE.

In 1884 I had my wagon repaired, (a wagon that had run 25 years.) New felloes were put on all the wheels and spokes in some. I took the felloes off three of the wheels, put them in a cauldron kettle containing raw linseed oil and brought it almost to a boiling point and kept them at that temperature in the oil four hours. When I took them out they seemed much harder than the felloes on the wheel not placed in the oil. I had the tire set upon all, used the wagon for four years and on the three wheels did not have to have the tire set during that time, while on the odd wheel I had to have it set every year. Were I to build a wagon for myself I would soak every part of the running gear in boiling oil for at least three or four hours. I had a light skeleton, weight 125 pounds, made. The felloes were soaked over-night in boiled linseed oil. This was run eight years before a tire was set, and that was because it was removed to put in a spoke that was broken, and some of the tires were run 13 years without setting.

Chautauqua County, N. Y.

FROM HENRY IVES.

The soaking of wagon rims in linseed oil is very beneficial, both preserving the tim-

ber and saving expense for re-setting the tire. To do it effectually the oil should be heated in an iron trough, keeping fire under it, while the wheel is suspended over it so as to be revolved slowly in the boiling oil; this should be done before the tire gets loose, then it prevents its loosening and is best done before the wheel is painted. Thus done it is a very economical practice.

Genesee County, N. Y.

FROM JAMES PERKINS.

I have for the last eight or 10 years adopted the practice of soaking my wagon wheels in hot linseed oil; the results have been most satisfactory. I have a wagon so treated six years ago which has been submitted to all sorts of roads and weather and the tires are as tight as the day they were put on.

Princeton, N. J.

FROM T. B. TERRY.

I had the rims of wagon wheels soaked in hot linseed oil until they would take no more, when the wagons were made, 10 to 20 years ago. Every spring we paint the rims. Tires have *never* become loose, and wheels are about as good as new to-day. I smile when I meet a farmer who is hammering at his tires or pouring on water to tighten them! I feel that I am 20 years ahead of him. But I have been there in times past.

Summit County, O.

FROM C. T. LEONARD.

I have a wagon that for 10 years has stood out-of-doors from May to November. During a hot day each summer it receives several heavy coats of boiled linseed oil; it is in a perfect state of preservation, every tire is tight and never received a nickel's worth of repair.

Ashtabula County, O.

FROM E. DAVENPORT.

I have tried setting tires with linseed oil and have not succeeded. First it is difficult to tighten the tire by using oil, and, again, the particles of sand that work in between the felloe and the tire are still there and immediately begin cutting and wearing the felloe, and again loosening the tire. I believe in paint as a preventive of loose tires but not in oil as a cure, at least in the soil I am accustomed to.

Ingham County, Mich.

FROM H. H. WING.

I have had no actual experience in soaking the rims of wagon wheels in oil, but I have had friends and neighbors who have had good results from the use of both linseed oil and crude petroleum in preserving the wood of the felloes and tightening the tires. As I have seen it practiced a tin vessel a little thicker than the wagon wheel and of the shape shown at Fig. 241, is used as a receptacle for the oil, and the wheel being supported on a jack is turned in the oil. In this way the felloes are treated rapidly and efficaciously and with no waste of material.

Cornell University.

The Poultry Yard.

Farm Rations For Poultry.

"The experts tell us that wheat is the best and cheapest food for egg production. It is my belief that most farmers feed corn to poultry with excellent results. I should like to hear from farmers as to the value of these two grains."

FROM A. L. CROSBY.

This inquiry came just as I had finished an experiment to find out how many eggs there were in a bushel of corn. In one of my hen-houses there were 22 hens and four half-grown chicks. They have no range except a small yard perfectly bare of vegetation. They have been laying without intermission since last November and about half of them sat once or twice in the spring. The experiment began August 17, and continued just 12 days; the hens were molting and the weather was warm. I had just broken six hens from sitting and during the 12 days shut up six more. Their feed was whole corn and skimmed milk—all they would eat—and a handful of grass and weeds each day. They ate exactly one bushel of corn, drank 18 gallons of milk—say 150 pounds—and laid 123 eggs. In the West skimmed milk is valued at 20 cents per 100 pounds: here I think it is worth more, say 25 cents; this would make the milk cost 37 cents for the 12 days. The eggs were worth a cent and a-half each, or $1.84; deducting 37 cents for the milk we have $1.47. Can we credit this all to the corn? I think not, but I do think that the corn should be credited with the larger part of it. I once kept an account for one year with 16 hens fed entirely on corn as their grain feed—no milk—and they paid a net profit of $1.25 each over the cost of the feed: this profit was almost entirely from eggs, as we raised but very few chickens that year.

I know that corn is a good egg-producing feed and also that, as the RURAL says, the experts all say that wheat is the best egg-producer and that corn is too fattening. My experiment to be complete, should have been continued 12 days longer and the hens should have had nothing but water to drink, but so many of them wanted to sit that it could hardly have been a fair test. Next winter I hope to find out how many eggs there are in 100 pounds of skimmed milk and also which is the better egg feed, corn or wheat. But I feel safe in recommending whole corn for hens, notwithstanding it is said to make them so fat that they won't lay. Some of my hens are as fat as they can get, and it does not prevent them from laying; neither does moulting, as one of the fattest hens has so few feathers on her that she looks bare, and yet she is one of the best layers. It will be found in the hen business as in all other kinds of stock growing that some well-established axioms have been allowed to stand on very slight foundations.

Catonsville, Md.

FROM MRS. L. C. MORSE.

My hens are fed on corn, whole and cracked, every day in the year—two rations in the winter and one in the summer. One gill per fowl as a ration. They have a common run in the summer and plenty of water the year round. The result is more or less eggs every day. The breed is Plymouth Rock with a Brahma and White Leghorn strain for variety. The chicks are fed the same as the hens from the time of hatching till they are guillotined, the cracked corn for them being, of course, finer than for the hens. I have fed wheat with good results, but "well-enough alone" is satisfactory.

Westfield, N. J.

FROM MRS. E. A. FASSETT.

Last winter we kept 50 hens. I like variety of feed. Wheat is good, but this is not a wheat-growing locality. If it were I don't think I should like wheat alone. I use injured wheat for common feed, but the greater the variety I have the better I feed, giving about as follows: Morning: a good feed of dry corn-meal dough warm, with occasionally a little red pepper; dinner: whatever scraps of boiled potatoes or anything else are left from the table. I give oats also and some sour milk to drink, and in winter plenty of good water with the chill taken off by adding a little warm water to the cold. Injured wheat warmed by putting it in a pan and setting in the oven is fed just before the fowls go to roost. With plenty of such feed we get plenty of eggs. We fattened our poultry—turkeys and chickens—last fall with inferior wheat; but just before we dressed them we fed corn-meal in the form of warm dough.

Hancock, Vermont.

FROM PORTER COLBY.

In our neighborhood wheat is not used very extensively as poultry food; but the few who do use it like it much. A grain firm in this place have sold two car-loads of what they call frosted wheat since January 1, 1889. Their price now is, by the ton, $1.25 per cwt; single cwt. $1.30. Some of this is used in adjoining towns. Corn used to be almost the sole feed for poultry about here; but now for eggs, we use about two-thirds bran and one-third scalded meal for the morning feed, and at night, two-thirds oats and one-third corn. Some use bran and middlings for the morning feed and some do not use more than one-fourth corn for feeding at night. There are two men in our town who keep from 500 to 1,000 fowls each; they buy their grain by the ton and feed some wheat.

Milford, N. H.

FROM O. K. LANE.

Wheat for laying hens, or any other fowls, is without an equal; but feeding it can be overdone, as fowls crave a varied diet. I have fed them wheat a few days; then they showed a preference for peas, or buckwheat. As eager as fowls are for fresh meat, they soon want a change to oats, corn, and wheat. So they leave the cabbage to taste the tomatoes; then curds. In eastern Illinois eggs sell for 10 cents per dozen and in winter for 15 cents; but it is too cold to ship them. Hence it doesn't pay to feed wheat. Eggs often sell for five cents per dozen. But few farmers pay any attention to their fowls.

Vermilion County, Ill.

FROM G. W. DREW.

Wheat is no doubt superior to corn for egg food, as corn alone is too fattening, but I think the majority here feed corn. Our aim is to feed no two meals alike in succession. We feed wheat, oats (scalded), barley, provender, wheat-bran, cracked corn, boiled vegetables, and corn (always at night,) with plenty of shells and bone. From this kind of feed we get the best results. Surprise a hen with kindness if you want her to lay.

Birmingham, Conn.

FROM C. S. VALENTINE.

Having lately changed my neighborhood, I cannot say much as to the facts of the case just here, but in that part of the country that I am most familiar with, viz, Western New York, farmers who feed wheat to their hens are about as scarce as hen's teeth. They consider it more expensive than corn, not seeming to realize that the same bulk will "go" nearly twice as far, and it is extremely difficult to convince them that the wheat is any better than the corn as an egg-producing food. Almost ten-tenths of them feed nothing but corn during fall, winter and spring, letting the hens pick their living throughout the summer. My own opinion is shown by my practice: I feed no corn except in the coldest weather, and then but once a day. I work in all the boiled small potatoes, turnips, etc., I can, mixing with them corn-meal, ground oats and bran, while ringing the changes on wheat, oats and buckwheat for the grain feed.

Farm Topics.

SOME CROP ROTATIONS.

WHERE THEY PUT STABLE MANURE.

ITS EFFECTS ON POTATOES.

FROM E. L. BASS.

As to crop rotation, I make my meadows give heavy crops of hay for about six years by giving them a good coat of manure when they are seeded down, and top-dressing them two or three times. I then plant the land to corn or potatoes for one year and manure lightly, relying more on artificial fertilizers, especially for potatoes, as I am confident that the application of stable manure tends to diminish the proportion of good, marketable tubers. The next year I sow barley and grass seed, using eight pounds of clover and 12 pounds of Timothy to the acre, and if the land is moist some Red-top also. I apply more manure the season when I stock down the land than I do the year previous, as I wish to reap the benefit of it principally on the grass crop.

West Randolph, Vt.

FROM V. A. SHANKLAND.

This county (Berrien,) pours into South Water Street, Chicago, a continuous stream of fruit, vegetables, etc., from the opening to the closing of navigation. In all the region about Benton Harbor and St. Joseph farm husbandry is "mixed." Grain, hay, stock, large and small fruits, garden truck etc., can be found, in almost endless variety, on nearly every large farm. For my own part I have 130 acres under this mixture:

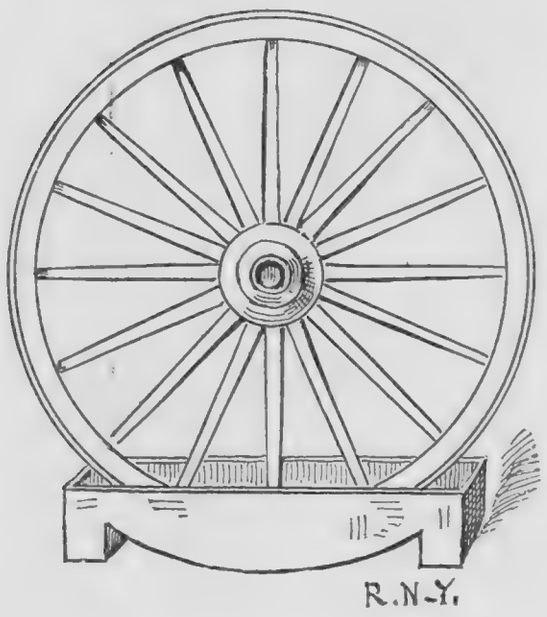

Fig. 241. SEE PAGE 639.

but make a specialty of seed wheat, potatoes and grade Jersey cows; and I would feel mortified should any neighbor—even a "RURAL" reader (or editor)—beat me badly on either of these specialties. This year I can report a potato field of 3½ acres, that will yield about 300 bushels of marketable potatoes to the acre. It was cultivated, but not hoed, and has not been manured for 10 years except that one-fourth of an acre of the present crop received one quart of mixed ashes and hen manure on each hill before the potatoes were up—an experiment that promises a good lesson. Success was mainly due to *marking out.*

My barnyard manure is permitted to rot, and is applied mostly about the fruit trees, and strawberry beds, and also to help the wheat, potatoes, tomatoes, etc. I spread it upon the surface after plowing and work it in with a spring-tooth harrow or a cultivator. I stick closely to a three-year rotation, as follows: 1. Grain—wheat, oats, buckwheat, seeded every time with Mammoth Clover and Timothy. 2. Hay—one cutting. All aftergrowth is plowed under in the fall. 3. Hoed crops—corn, potatoes, beans, tomatoes, etc., and then I go back to grain and clover. Under this system, in seven years my land has come up from a renting value of one dollar per acre to a renting value of seven dollars per acre. It is but fair to say that the RURAL has been a great help to me, not only in regard to my specialties, but in the whole field of my farm life and work.

Berrien County, Michigan.

FROM M. MORSE.

I have no regular crop rotation nor do I think I can have one without often deviating from it. Most of my crops are grown for the canning factories and I keep a large portion (nearly half) of my arable land under cultivation. I have been on my farm only nine years, and when I took it the total product was only five to six tons of poor hay. I had to depend wholly on commercial fertilizers at first, and even now more than half my crops are grown with them. I have used from $400 to $700 worth of them each year since I have been on the farm. I generally dress the land when I seed to grass, with stable manure, believing it may have a more lasting quality than fertilizers and the weed seeds in it will trouble me less. Much of my grass land has been seeded with fertilizer, about half a ton per acre, and annually dressed afterwards with 400 to 500 pounds per acre. The result has been as good as where stable manure has been used. When I have more manure than I need to seed down with, I spread it upon land intended for corn, but I do not use manure on potato land. I think the quality of potatoes grown upon green manure is not as good as when they are grown with fertilizer—I only think; I do not know. My first crop after grass is corn, and as corn occupies more than half the cultivated land, it is corn after corn, sometimes for two or three years. I grow no small grain, except winter rye, which I sometimes sow after the corn is harvested, and usually cut for green fodder or hay the next season and plant again to corn or some other crop, as cabbage or tomatoes or squash; in fact, whatever crop the land and market promise to give the best returns for. I am not very systematic, and my practice would not be good for many to follow. I am, and have been, for several years, giving considerable attention to fruit culture, as it suits my taste best.

Medway, Mass.

FROM J. TALCOTT.

I put my stable manure on sod ground in fall and winter for corn and potatoes, spreading as put on. We plow it under for corn and potatoes just before planting. Why? Because we think it the best way. The corn or potato crop gets the most benefit from it, when it is most needed, when the corn is filling out its ears and when the potatoes are setting their tubers. We plow a little deeper for the oat crop, thus getting the manure and inverted sod finely mixed for the crop and for seeding, because seeding with oats is generally practiced here. Sometimes the oat stubble is plowed under for winter wheat, and in that case a little fine manure is usually spread on the surface and dragged in for the benefit of the wheat crop, and also for grass seeding. I have known a fine crop of wheat grown on oat stubble where the manure was plowed in; in fact, the best crop of the season in this vicinity one year was grown in this way.

Rome, N. Y.

FROM A. B. SAUNDERS.

I use no crop rotation whatever. My main and sole object the year around is to gain and maintain a grass crop for grazing. If any crop is raised it is preparatory to seeding to grass, and it is not considered the highest object to which I am trying to attain. The main part of the stable manure is spread upon the young grass crop. This process is improving my upland, and as most stock is in good demand it is giving fair returns to the land in the form of manure as well as to the purse.

Guysville, Ohio.

FROM W. M. BENNINGER.

I have no regular rotation on my farm. I turn the poorer grass fields and put in corn and potatoes, manuring heavily with good stable manure. I get the best results from good stable manure. I raise very little winter grain and oats. Such crops don't pay

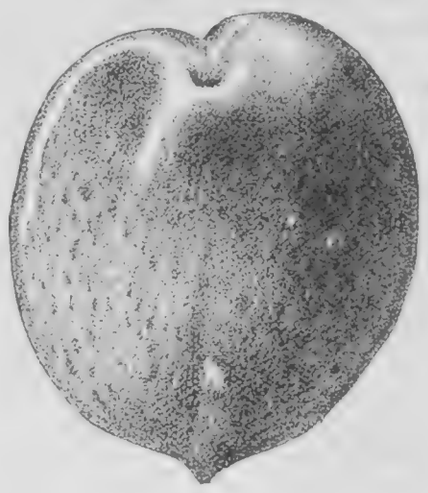

Fig. 242. SEE PAGE 641.

here. All I sell from my farm is milk, cream, butter, potatoes (mostly for seed) fruit, garden vegetables and stock. I have made it a rule not to sow or plant any crop unless I can manure it well with good stable manure, and I use stable manure on all crops. I make and treat my manure as follows: to bed my cows and all horned cattle, I buy dry sawdust at 15 cents a load from the school-slate-frame factories. The gutters in my stable are very tight so that the dry sawdust aborbs and retains all the liquid manure. This manure I put on the land as often during the season as I can. Afterwards the land is plowed and harrowed with a spring-tooth harrow and smoothed with a Thomas smoothing harrow. For potatoes I manure the land well in the fall on top and turn it under, and manure again in the spring on the top with the above described cow manure. I used some lime and wood ashes in the trenches when I planted my potatoes this spring, and on some I used commercial fertilizers. I can see no difference. The tubers are all about half rotten; otherwise the crop would be very heavy. In a favorable season I raise about 300 bushels to the acre.

Walnutport, Pa.

FROM F. W. BALL.

After potatoes I seed down with oats, then mow or pasture from one to three years. There is going to be a change. The rotation has been corn first; then potatoes, followed by wheat or oats—mostly wheat. I used stable manure on the potato crop. As it is our main money crop I wished to get as large a yield as possible and the manure left has been plenty for the oat crop following. I have had a good many scabby potatoes, however, every year, and charge the mishap to the manure, so I shall change the programme a little, using my stable manure hereafter as a top-dressing for grass; then I shall mow one year, and then plant to potatoes.

Erie County, N. Y.

FROM CHAS. CHAPMAN.

Believing that the rotation of crops on any farm should have for its object an increase of income each succeeding year for the farmer as well as the improvement of the soil and be also influenced by the nature of the soil and the climatic conditions peculiar to the section, I have practiced the following plan for years, and as yet have no reason for abandoning it:

All the barn-yard manure possible is drawn during the winter on a clover sod from one to three years old. It is drawn and spread during the winter because experience has proved that we get better results from treating it in this way, and the cost of drawing it is less during the winter. The field is plowed and planted to corn in the spring. The following spring it is sown to barley and in the fall to rye or wheat. If rye is sown, four quarts of Timothy seed are sown in the fall per acre, and in the spring four quarts of Red Clover and one quart of Alsike.

With wheat no grass seed is sown until spring. All stable manure left in the stables and what has accumulated during the summer is used as a top-dressing on the wheat and rye in the fall. These fields are mown for one or two years and pastured one year, when the rotation is repeated. This year it was necessary to mow the fields on which rye and wheat were grown. All straw and hay are fed on the farm excepting rye straw. The only change of late years has been the addition of more bran to the stock feed. The result of this system of rotation has been an increase in the amount of stock kept (mostly sheep), thus returning to the soil all the plant food taken from it and making an increase in the yield of the crops per acre. I have never raised potatoes largely, but from frequent trials I have found more decayed and scabby potatoes where stable manure was used.

Schuyler County, N. Y.

Field Crops.

STABLE MANURE and POTATO ROT

DOES MANURE INDUCE ROT?

VIEWS OF FARMERS.

"Some of our correspondents claim that in a season like the one just past, stable manure will induce rot in potatoes. That is, on soils at all inclined to be damp, the rot will be worst where there is most stable manure. Have you noticed this?"

FROM C. M. LUSK.

I have noticed the same thing. Several years ago potatoes rotted very badly here, and most of my potato ground ha been manured with coarse horse manure lowed under and the rot was worse there than where I did not manure. Still I obtained more sound potatoes per acre there than where there was no manure. My land is a sandy loam.

Broome County, N. Y.

FROM E. G. WALLIS.

My experience has been that potatoes have rotted worst where most manure was plowed under; and that the white potato rotted worse than the Blush, but the past season I think the white potato stands ahead. The Blush are very small.

Onondaga County, N. Y.

FROM J. H. TIBBETT.

I do not consider manure the direct cause of the potato rot; but I think it presents the conditions most favorable for its development. In this section we do not consider it safe to manure potato ground in a wet season like the past. From my observation I think the disease attacks the vines first and is carried through them to the tubers.

Saratoga County, N. Y.

FROM J. H. LAMPMAN.

I find a few more rotten potatoes where I put stable manure than where none was used; but it is clay ground and the variety is the Rural Blush; so I think the Blush would be more apt to rot than my Beauty of Hebron which are on sand. I will continue to use good old stable manure if I have it, well worked into the ground before planting, and then some special Potato Fertilizer in the hill or drill. My Rural Blush are a good crop with such treatment, although many rotted.

Greene County, N. Y.

FROM HENRY IVES.

A liberal application of manure before planting, has seemed to cause rot in years when the malady prevailed. But this may be only a secondary cause, for the rankest growth and yield, induced by such manuring, are sure to be the worst affected. This is more noticeable too when the manure is freshly applied, and before its strength is distributed equally through the soil. To remedy this, I find it is safer either to apply it to the corn crop of the year before, or at least to put it on the ground the fall before, so that its strength may get well incorporated with the soil.

Genesee County, N. Y.

FROM J. W. WICKHAM.

I have always used fertilizers with stable manure for potatoes; so I could not say if stable manure alone used heavily would cause rot. My experience is that the more heavily potatoes are manured, the more liable they are to rot. I believe that the rot in my potatoes this season came from the destruction of the vines by the Flea-beetle more than from the manure used.

Suffolk County, N. Y.

FROM BENJAMIN WEED.

I put about 20 loads of barn-yard manure to the acre on my potato ground this year. The tops died when the tubers were about half grown. I have discovered very little rot so far and the manure has not had any tendency to cause them to rot.

Wayne County, N. Y.

FROM C. H. EVERETT.

I do not think the RURAL's correspondent has got to the bottom of the matter when he says that stable manure will induce rot in potatoes on soil inclined to be wet. Some think, because their potatoes have rotted the worst where the manure was, that the manure was the cause of the rot. Whenever there is an unnaturally rapid growth of vine or tuber, whether it be due to the application of manure or to the condition of the soil or a favorable climate, rot is very likely to occur. In such a case something seems to be lacking in the potato. Some claim that the starch does not form as fast as the potato grows. I am much inclined to agree with them that the trouble is due to something of this sort. Give me the manure and I will take the chances of rot.

Steuben County, N. Y.

FROM E. G. BRICK.

I have never noticed that stable manure

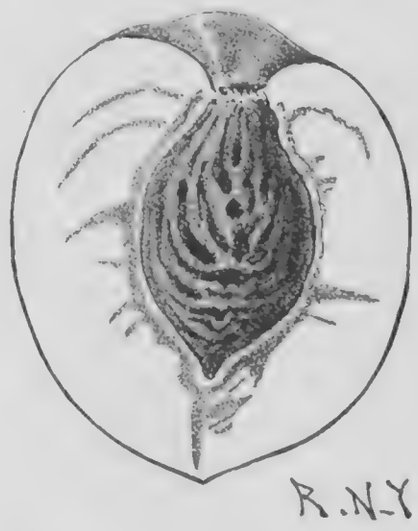

Fig. 243. SEE PAGE 641.

induced rot in white potatoes, and so cannot say anything positively.

Salem County, New Jersey.

FROM ELIAS P. JOHNSON.

On inquiry I do not find any potatoes planted directly on stable manure as was formerly done, the scab having put an entire stop to the practice. The worst rotted field about here was fitted for tobacco. A

very heavy coat of stable manure was put on the surface and thoroughly worked in with a wheel-harrow. No fertilizer was put on the hill. The general way here is to pulverize a fair coat of manure in the surface soil and use ashes and some of the potato fertilizers, or phosphates, in the hill. I do not know of any manure being plowed under lately. My own land is sandy. I use no manure; but plow a trench, drop about 25 bushels of ashes and 500 to 800 pounds of Buffalo potato fertilizer in the trench on each side of the potatoes and cover with a tobacco ridger. I have not had 10 bushels of rotten potatoes in 25 years. I raise only 50 bushels per year. There has not been much rotting about here in the last three weeks.

Windham County, Vermont.

FROM G. M. BENNETT.

Not having used any commercial fertilizer for potatoes this year, I cannot tell if it prevents rot, but I don't think stable manure causes it. My patch was first attacked by the Flea-beetle which perforated the leaves so badly that the bugs gave them up. Then came the blight and the wet weather caused the fungous growth and rot. Slipshod farmers have not suffered much for the reason that they had fewer potatoes to rot.

Fairfield County, Conn.

FROM G. H. GRIFFING.

My practice for several years has been to plant potatoes with commercial fertilizers exclusively, believing that stable manure induces rot. When I have planted early and used nothing but fertilizer, I have invariably had good crops, in seasons when my neighbors, who used barnyard manure freely, have lost by rot.

New London County, Conn.

FROM G. W. GOODRICH.

Potato growers in this locality are generally of the belief that barnyard manure will induce rot in potatoes, especially in a wet season; and when the vines begin to turn black from the effects of the blight, about the first of August as they did this year, a larger percentage of rotten potatoes will be found on fields where barnyard manure has been used than in adjoining fields, where fertilizers were used. My personal experience is that a complete fertilizer applied in the drill at the rate of 800 pounds per acre, will give a larger crop of potatoes, more free from scab, and less liable to rot, than a fair dressing of stable manure. The more stable manure is used for this crop the greater the chances for a crop of rotten potatoes.

Lackawanna County, Pa.

The Vineyard.

Notes from the Rural Grounds.

THE EATON GRAPE.

WHEN the R. N.-Y. from its own trials discovers that a novelty possesses marked merits, it can not rest until it has done all in its power to bring those merits to the notice of its readers. We have frequently alluded to the Eaton Grape. Our only specimen was received from the late John B. Moore of Concord, Mass., October 20, 1885. The vine has proven perfectly hardy, as vigorous as the Concord with larger leaves which are free from mildew, continuing healthy until destroyed by frost. This is its second year of fruiting and it must be considered that what is here said regarding the Eaton is merely the opinion formed from a comparatively brief trial. It has been a trying season for grapes in this locality. Rose-bugs existed in great numbers and so injured the blossoms that few bunches of any kind are perfect. The incessant rains have caused most varieties to rot and mildew that hitherto have yielded fair crops. There is not at this time a perfect bunch on our Concords. Delaware which usually thrives well here lost its leaves so early that not a bunch will ripen. The Eaton has ripened perfectly and its season seems to be a few days earlier than the Concord's. The berries hold well to the stems; they neither mildew nor crack more than the Concord though of the largest size—larger than shown at Fig. 240, which is a photographic illustration of an *average* bunch, grown, please bear in mind, during an unfavorable season. The writer has just picked a bunch that would weigh nearly twice as much.

The skin of the berry is just like that of Concord or Worden—neither firmer nor more tender. The pulp is less than that of Concord or Worden, and that is not so tough. The berry is for the most part juice—not of a high quality; not so sweet as that of Concord, but free, or nearly so, of the foxy flavor of that popular variety.

We would lay stress upon the following characteristics: Health and vigor of vine; size of berry; size of bunch. The berries cling firmly to their peduncles. The bunches and berries average larger than those of any hardy, healthy black grape ever grown here. It ripens *fully*, a few days (say three) before the Concord. Finally, we would commend a trial of this grape to all of our readers, since we have found by 15 years of experience that those grapes which thrive in this valley will thrive in almost any section of country where grapes are grown.

The history of the Eaton, in so far as it is known to the writer, is as follows: It was grown from Concord seed in the year 1869 by Calvin Eaton of Concord, N. H. It was purchased by John B. Moore & Son, of Concord, Mass., in 1882 and first offered to the public in 1885 or 1886. Bunches have been exhibited at the Massachusetts Horticultural Society and elsewhere weighing from 20 to 30 ounces.

The Eaton is a black grape, often measuring nearly an inch in diameter, with a dense blue bloom. The bloom is well shown in our illustration.

Pomological.

A NEW NECTARINE.

ON July 11, we received from J. L. Normand, of Hillside Nursery, Marksville, La., a seedling nectarine. It is said to be proof against injury by the curculio as it has been practically exempt for the last four years. It is said to be an excessively prolific variety and the fruit ripens all together and very evenly. The carrying qualities of this new seedling will be understood when it is said that the specimens were received at this office in perfect order. The quality is excellent. The illustrations (Fig. 242), with a cross-section at Fig. 243, shows the average size of the fruit entire and in half-section.

Everywhere.

A PLEASANT VOICE FROM CALIFORNIA.

SAN DIEGO, San Diego County.—I was just now looking over some relics of our old eastern home, when I came upon the familiar face of the RURAL NEW-YORKER. In a flash I was back again in the old times—so old—five years ago—10 years ago—when the RURAL used to come to us on the banks of Lake Erie; and the boys looked it over, and then went out on the lake for a sail. Now, all the boys, except one, have gone away beyond the lakes and oceans of this world. The links to the old times are very precious, and looking over the bright pages, they seemed to greet me with such whole-hearted remembrance and charming cordiality that I said: "I will venture to write to the RURAL again, as in the old times." So here, upon this western edge of our country, with the blue Pacific melting away into the southern sky, I will tell a little how every-day matters go with us pioneers on this Point, which has seemed so wondrously beautiful to me since I first stood on its hights and looked off.

Point Loma is about five miles long by two miles at the widest perhaps, lying north and south, with San Diego Bay on the east, and False Bay on the west. It is quite broken and precipitous in places, though the greater part consists of fine slopes and rolling land growing gradually narrower and higher, till it comes to a point 450 feet high at the southern extremity. Here stands the lighthouse, the property of Uncle Sam of course, and he also owns the Point for about two miles back, it having been donated to him by the city a long time ago. It is a rough piece of ground to be sure; but it is full of possibilities, and if I had as much money ahead as Uncle Sam has, I would make it "a thing of beauty," a pleasant place to look upon as well as to look off from. The view from this ridge of land is incomparable; everybody wants to visit the lighthouse, and the approaches to it should be better.

With a few exceptions, the whole Point is in a state of nature, or worse; for 40 or 50 years ago, everything that could be called a tree was cut off for wood by trading vessels, and now we have only a scrubby covering of bushes. The soil is good, very good; and everything grows well, if it can only be left alone; but the birds and rats and rabbits think it so good of us to raise new kinds of nice, tender things, and they take hold and eat, and we have to be forever on the alert, and have to console ourselves with the thought that the country is new, and that things will be better bye and bye. Sitting on our veranda, and looking off, it doesn't seem as though the country were new. Four hundred feet below we see the van of a great commerce,—ships and steamers gliding into the bay, and around to the city wharves five miles farther on; and the electric lights of San Diego give us moonlight every evening; but yet we are pioneers here all the same; and the country is new, and we have wild animals to fight, as they had in Western New York 60 or 70 years ago. Along this Point the wild-cat roams in all its native freedom and ferocity, and the coyote howls, not only at night, but at high noon when the clouds are lowering.

"Aren't you afraid of the wild-cats and coyotes?" asked the carpenter who had been camping over here, building our house.

"Oh, no," I said, bravely enough; and really I had not the least apprehension of trouble from that quarter; but the very first day that we had our hens here, a wild-cat jumped into the midst of them as they were eating near the door, and carried one off in triumph. I happened to be looking out of the window, and saw it, and making some kind of an exclamation, I rushed out, and my boy rushed after me. and followed the cat, but there was no fence around our place then, and the raider was soon lost in the bushes. It was too bad! We had just six nice hens, bought from somebody who had brought them all the way from Iowa, and we had refrained from eating them ourselves because we wanted the eggs, and those were the days of "the boom," when chickens were scarce, and we were going to raise more for ourselves; but now that cat had the hen for his supper, and the prospect was dark ahead. The gun was kept in readiness, but somehow the cats never appeared to the right person. Early one morning, as I opened the door, there stood two great wild-cats, in the drive-way a few rods off. I supposed they would run like a flash at sight of me, or slink away into the bushes, awed and abashed; but, instead of that, they just stood still in a complacent fawning attitude, like two strangers whose motives were likely to be misunderstood, and who were anxious to set themselves right. They twisted their heads around, and wagged their tails, as though they would like to come to a parley, and to establish some ground of mutual good fellowship; but I said: "S's' cat!" then threw a piece of board at them with my left hand, after which they reluctantly turned and went on down the road.

Then again, a little before dusk one night, as I went out to attend to my plants, there stood a great wild-cat. He had just come up the steep declivity leading down to the sea, and evidently wanted to make an explanation about something. He swung his long tail around for a flag of truce, and put on a most plausible expression of countenance, as much as to say: "We are old settlers around here—honorable gentlemen, who can always be depended upon. We would like to remove any unpleasant impression you may have received, and to be on calling terms with you, if you are to live among us. Those sneaking coyotes"—Here, I motioned him away, and threw a chip after him; when he went off on a leisurely, dignified trot, with an air all over him which said: "You are slighting one who would gladly benefit you." They have done us much mischief since, crowning all by eating up our cat and kitten; leaving us exposed to the ravages of the rats and mice. These last are fairly shut out of the house; but outside they cause the proprietor of the grounds many heart-sinkings. He is anxious to sit under the shadow of his own trees and vines, and to eat their fruit; but these rats are constantly gnawing off the choicest young trees and plants.

Oh! it is vain to seek for anything like Paradise in this world. Here, in this delightful climate—no burning heats, no biting cold, there are plenty of other things to distress and to make us look away with longing eyes to the world we have not seen.

P. V.

RURAL SPECIAL REPORTS.

Canada.

WHITBY, Ontario, September, 12.—The potato crop in this county is in good condition except where planted in low, rich land where considerable rot exists. The probable production will be about 70 per cent. of a full crop. The crop at Cape Breton is very much below the average, there not being nearly half a crop, and what there is, is rotting very badly. In New Brunswick and Prince Edward Island the crop is also short and much rot prevails.

J. K. G.

Illinois.

SHELBYVILLE, Shelby County, September 9.—The potato crop is better than an average, both late and early kinds. None are rotting as far as heard from in this section of the State. The Colorado Beetle made its appearance as soon as the plants were up, but the application of Paris-green once, and the continuous heavy rains throughout the growing season settled the pests. I have heard no complaints with regard to the Flea-beetle. I have dug my Rural No. 2 Potatoes, and got 18 fine, large tubers the product of the one small potato, which contained four eyes and was cut into four pieces, which were planted one eye in each hill, one foot apart after the RURAL trench system.

E. J. M.

Indiana.

PENDLETON, Madison County, September 10.—Stock of all kinds are in good condition. Horses, cattle, sheep, and hogs have been healthy and are generally fat. This may be accounted for by the abundant corn crop of last year, the mild winter, and the frequent rains of this season. Horses of common quality and size are low, heavy draft horses are worth from $100 to $150; stylish carriage horses bring about the same price. The prices of cattle are still away down. Local butchers pay two to 2½ cents per pound for choice young stock on the hoof. Heavy steers are worth three to 3½ cents. Fresh milch cows can be bought for $20 to $30 each; good sheep for three to 3½ cents, and hogs for four cents per pound live-weight. The weather is rather cool for corn, but favorable for seeding wheat. Our farmers prefer to drill their wheat in the first half of September.

S. W. H.

Iowa.

DES MOINES, Polk County, September 9.—Our great State fair is past—and it beat all previous records. The weather was fine and the people turned out well. The gate receipts were $10,000 or $12,000 more than last year. All the various departments were well represented. On Sunday Dr. Thomas, of Chicago, preached a very able sermon on the grounds, and on Wednesday Dr. Talmage, of Brooklyn, gave a very able lecture on Time. These divines and the great trotting colt Axtell were the leading attractions of our fair. Of course we had the usual number of side-shows, picked-pockets, gamblers and tricksters of all stripes on hand. Now that the fair is over, we need rain to revive our grass, furnish stock water and finish up our crops of late cabbage and turnips. We have had no frost yet; and our corn is past the danger line. We have a great abundance of watermelons, tomatoes and grapes. I see no reason to change my opinion, expressed in a former report, in regard to our potato crop. Our onion crop will be a short one as compared with that of last year.

F. S. W.

New York.

GENESEO, Livingston County, September 16.—The weather in the valley of the Genesee River has been remarkably fine during the past month. Corn, and even late planted beans are mostly beyond the danger point from frost and promise an average yield. The wheat crop is more than an average in yield and berry. Early potatoes are a failure from rot; late varieties on heavy soil, are affected in the same manner. Apples in part of the county are a failure; in other parts there will be from a-third to a-half a crop; winter varieties are falling prematurely. The hay crop is large, and so is the oat crop. Preparations have been made for putting in a large acreage of winter wheat and farmers are busy seeding. There is a lamentable neglect in the county among farmers in breeding standard, compact, fast-walking draft-horses, especially of the Percheron and Shire varieties. Among 40 varieties of peaches that suffered from a late freeze on my grounds, the following have borne heavily: Beatrice, Early Rivers, Morris White, Oldmixon Free, Mountain Rose, and Hill's Chili and several seedlings. Among 30 varieties of plums the following

have behaved best this season: Lombard, Orleans, Smith's, Victoria, Reine Claude de Bavay, Coe's Golden Drop, Prince Englebert. Grapes are, for the most part, a failure, except on very highly favored sites, and under the protection of trees. Late-blooming varieties escaped in part, where the earlier succumbed. Vines containing foreign blood have suffered from mildew more than in drier and warmer seasons.

R. T.

MELROSE, Rensselaer County, September 16.—Crops in this county have been better than for many years, with the exception of potatoes, which are not more than half of an average. They are bringing 50 cents per bushel. Hay brings 65 cents per 100 pounds; rye 50 cents per bushel, and oats about 35 cents per bushel. My Rural No. 2 Potato weighed two ounces, and four pieces were planted May 1st in as many hills in a trench, 15 inches apart in good garden soil. There was a great growth of vines, one stalk measuring two inches in circumference. There were no blossoms, nor were there signs of any. The tubers were dug August 25, and the result was 17 potatoes weighing 4½ pounds all of marketable size, the largest weighing 13 ounces; two others weighed 12 ounces apiece. They are very fine. All who see them call them beauties. A. H. S.

THE FARMER'S CLUB

ANSWERS TO CORRESPONDENTS.

[Every query must be accompanied by the name and address of the writer to insure attention. Before asking a question, please see if it is not answered in our advertising columns. Ask only a few questions at one time. Put questions on a separate piece of paper.]

ADULTERATION OF FOOD STUFFS.

Several Subscribers.—Are the ordinary stock foods—bran, meal, "feed," etc., etc.—as sold by millers or feed dealers adulterated to any extent? Are efforts being made at our experiment stations to detect such adulterations?

ANS.—These questions have been referred to the following directors of experiment stations:

FROM DR. PETER COLLIER.

Our attention has been called to the fact that wheat bran is often adulterated with less expensive food products, and one instance has come directly under our observation. In the early part of the present year a ton lot of wheat bran was ordered for station use, and on examination it was found to be one-third or more buckwheat bran. Ground oats sometimes have a portion of the meal removed and the feeding value of such oats is much lessened. There are tricks in most trades, but whether this is a common practice among millers and feed dealers or not, I do not know.

Geneva Experiment Station, N. Y.

FROM DR. H. P. ARMSBY.

I have made no special investigations as to the adulteration of cattle foods, but have seen no reason to suspect that, as ordinarily sold, they are adulterated to any material extent.

Pennsylvania Station.

FROM DR. E. H. JENKINS.

Our investigations have not shown any real adulteration of bran, meal, etc. We have sometimes found fragments of seeds in bran, resulting, probably, from the grinding of refuse wheat with the bran. Such adulteration can usually be detected by one who has some knowledge of the ap pearance of seeds.

Connecticut Station.

FROM PROF. W. W. COOK.

So far as we know from our examinations and analyses, no adulterated foods have been put on the market in this vicinity. I do not think we have analyzed any cattle food that did not run fully up to the average composition of its kind, and in nine-tenths of the cases they ran over.

Vermont Station.

FROM DR. G. H. COOK.

In regard to the adulteration of cattle food, the station laboratory has had more than 100 samples of the different kinds of cattle foods for sale in the several counties of the State. These have all been examined, and none has been found which appeared to have been adulterated for fraudulent purposes.

New Jersey Station.

FROM PROF. G. H. WHITCHER.

I do not think the grain we buy is in any way adulterated. Corn-meal of course is ground from Western corn in our local mills; bran comes up in its analyses to what would be expected from average analyses as published by Armsby, Jenkins, and others; middlings, cotton-seed and gluten meal are also usually all that we have reason to expect. Of course, we may occasionally get goods that are damp; but so far we are satisfied that no systematic adulteration is practiced. I know of no way of guarding against such adulteration except by having analyses made of samples of grain and feed and in such cases we cannot be sure of the materials used; we can only tell the amount of nutrients per 100 pounds, and by comparing this with a table of the average composition of similar grains and feed, a very good idea may be formed of the probable purity of the analyzed feed.

New Hampshire Experiment Station.

FROM DR. C. A. GOESSMAN.

The various articles of cattle feed—as brans, meal, oil-cakes (cotton and linseed), gluten meal, starch feed, dried brewers' grains, etc.—which have come under my notice here, I have found, on the whole, of a fair character. The examination of these and others of a similar individual character, by means of a careful chemical analysis and of a careful microscopical observation promises a fairly reliable basis for our conclusions regarding their genuine character, for it offers a desirable chance of comparing our results in both directions with those obtained in case of a sample of undisputed origin or source. The uncertainty of the correctness of our decisions increases more or less with the number of different materials used in the compounding of the particular cattle feed under consideration. It is for this reason that I have advised on various previous occasions to discourage the manufacture of compound feed-stuffs for the general market. The highest feeding effect of our home-raised fodder crops can only be secured by supplementing each with reference to its particular composition for the special object in view. The safest and most economical course to attain that end consists in selecting from among our commercial concentrated fodders articles of a well-known individual character one or more best adapted to answer our purpose. To make a judicious selection requires not only a fair knowledge of the chemical composition of the different fodder articles at our disposal, but also a fair information concerning the approximate rate of digestibility of the several essential food constituents contained in each of them. Most of our commercial concentrated individual feed-stuffs have been carefully studied in both directions, and reliable facts are in reach of every farmer. Nothing of that kind can be claimed in regard to the majority of compound feed-stuffs sold in our markets. The best interests of progressive agriculture require the adoption of an intelligent course of observation in stock feeding.

Massachusetts Station.

ELECTRICITY ON OUR STREET RAILROADS.

C. B. C., Plymouth County, Mass.—I send the R. N.-Y. this clipping from a local paper. Is there anything in this idea? To what extent is electricity taking the place of horses on street railways?

"President Whitney, of the West End Railroad of Boston, declares that before long he will have 4,000 horses for sale—stock no longer needed upon his street lines, being ousted by electricity as a motor. The public has heard a good deal, first and last, about the damage to horses caused by the introduction of electric railways; but it seems to me that this wholesale crowding out, so to speak, of horse flesh from the highways is more significant than all frightening or demoralizing that has taken place. Here, after all, is the real horse difficulty, as connected with the innovation of electric roads. Horse buyers and sellers, farriers and blacksmiths, veterinary surgeons, harness makers, hostlers and towboys, hay and grain dealers, and without doubt many other artificers and tradesmen, may have considerable to say under this view of the case, while the Anarchists and Socialistic brethren, not to mention the extreme "labor" elements, will see in it only a new cropping out of oppression, and denounce the whole thing as another substitution of mechanical for human employment to the detriment of the last named."

ANS.—The R. N.-Y. believes that the development of the different forms of electric motors will have a remarkable effect on American horse breeding. The single Boston company mentioned in this note owns 217 miles of track, and runs 1,584 cars, so that the estimate of 4,000 horses is not far wrong. These cars hereafter will all be run by electricity. The street-car horse is of small value for farming or general teaming. The reason of this is that he does not know how to "back." Few people have any idea of the importance of our street railways. In July 1880 there were in 26 cities alone, 189 street railways, using 18,645 cars and 80,154 horses and mules. These railroads carried 1,434,057,595 passengers during the year. These are the figures for the 26 cities in the United States which have over 100,000 inhabitants. The smaller cities and towns with their more simple systems of street railroads will add at least 20 per cent. to this total. Four years ago there were but 7½ miles of street railway on which electric motors were used. July first of this year there were 575 miles and to this may now be added the 217 miles of the West End Company. The fact is that the development of electricity as a motive power within the past two years, has been absolutely without a parallel in the history of the world. Electric cars pass the R. N.-Y. office every hour, running on the same tracks as cars drawn by horses. The cars move silently and steadily at a touch. They can be stopped almost instantly. It is only a question of time when 90 per cent. of the horses now used on street railways can be dispensed with. What is to follow? How many men are required to care for 100,000 mules and horses? How much grain and hay do they consume every year? Every year the street railways need 30,000 new horses. Cut off this demand and what difference will be made in the horse markets? These are questions that concern farmers. On the other hand, what compensating advantages will come with the substitution of electricity? The question is a great one—full of thoughtful suggestion. There is one thing that may be said about the street-car horse—he is generally a "misfit," a failure at the task he was specially bred for. He is too light for a dray or too slow for a sulky or too shabby for a carriage, and in the majority of cases his unfitness is due to a mistaken idea in breeding—the belief that a scrub can produce a first-rate animal. The destruction of the market for such animals may result in the abandonment of such breeding.

STRAWBERRY PLANTS.

J. B. H., Shoshone, Idaho.—Please give me instructions through your columns as to the culture of strawberries; which sets should be transplanted and how cared for in the winter season, etc.

ANS.—Strawberries will succeed on almost any fertile, well-drained land, excepting muck. The land should have been in hoed crops for at least one year previous, and should be free from weeds, and in good condition. The deeper it can be dug or plowed, the better. For garden culture, the rows should be about two feet apart; for field culture, about four. The plants should be set from one to two feet apart in the row depending upon the variety and the season of planting; the later the plants are set, the closer they should be. They may be set any time of the year when new plants can be obtained. Only young, vigorous plants should be set, preferably from a new bed which has not been exhausted by bearing fruit. The bed should be kept thoroughly clean, and when the ground becomes frozen, should be well covered with straw, coarse, strawy manure, or other mulch, which may be removed in the spring, or worked down around the plants. Plants set soon may be permitted to bear some fruit next year, but those set in spring should have the blossoms removed to secure best results in fruit.

STARCH FROM POTATOES.

T. W. P., Barron, Wis.—Will you or some of your New York correspondents kindly give me some information in regard to the manufacture of starch from potatoes? The price ordinarily paid for potatoes, cost of manufacture, price received for finished product, market for same, etc?

ANS.—Starch is made from potatoes in large quantities in Vermont, New Hampshire and Maine. The profits of the business depend upon the quality of the potatoes, which must be rich in starch. Tubers grown in a northern locality, and which cook dry and mealy, contain the largest amount of starch, and are the best for the purpose. The "price ordinarily paid" would probably be the ruling market price, but at 25 cents per bushel for potatoes, the business affords a fair profit at six cents per pound for the product. The price of starch varies so that no certain price can be given. A mill in Vermont which works up 1,000 bushels per week, cost $3,000. A large amount of water is required in the manufacture, and this also furnishes the cheapest power. Five to 10-horse power is required. Small potatoes can be utilized if they are ripe, although large ones are said to give starch of better quality.

ABOUT HOLLYHOCKS.

C. F. E., Easton, Md.—1. When is the proper time to divide hollyhocks? The plants are two years old and I wish to secure the same varieties next year. 2. Can the same hollyhock plants be made to bloom year after year by dividing the roots, or is there a serious loss of vigor after the second season?

ANS.—1. As soon as they are done blooming in summer, also when growth begins in early spring. 2. The propagation of hollyhocks by division is a clumsy and often unsatisfactory method. By far the healthiest stock is obtained from seed. In order to perpetuate precisely the same varieties they are increased from cuttings of the flower stalks in summer or from cuttings of starting clumps in early spring. To obtain the summer cuttings, take some of the smaller or lateral flower spikes when they are about half-grown, and cut them up into one-eye pieces about an inch long, cut off the leaf, shorten the leaf-stalk and insert the cuttings in small pots or boxes filled with sandy earth and keep close and shaded for a week or two till the eye starts to grow and roots push out, then treat as young plants. Spring cuttings or rather "slips" are started in much the same way.

GLUTEN MEAL.

G. C. C., Manville, R. I.—I inclose a sample of what is called "gluten meal"—selling price 12 cents per bushel. What is it? How and from what is it made, and what is its feeding value?

ANS.—"Gluten meal" is the refuse from the corn used in starch and glucose factories, and is a nutritious and healthful feeding substance. Only a portion of the starch is taken from the corn, the hull and germs being left with a part of the starch of the kernel. The hull contains all the fat of the grain, and the germ, or chit, contains most of the nitrogen. The Connecticut Experiment Station's analysis gives it a value of $1.17 per 100 pounds, considering the best corn to be worth $1.10, and wheat-bran $1.04; but it must not be fed to excess, and care should be taken to prevent it from souring. Some have considered it objectionable for feeding milch cows.

THE PEACH OR ELM-BARK BEETLE.

E. W. F., New Albany, Ind.—Inclosed find samples of insects that are working on some of our peach trees, in this section. They bore small holes in the trunk and limbs, and when numerous enough they kill the tree. One nurseryman's young stock has been attacked. What is the name of insect and how can we get rid of it?

ANS.—This is the Peach or Elm-bark Beetle—Phlœotribus liminaries, Harris. The pests bore into elm and peach trees, forming tunnels or burrows about the size of small knitting needles. The beetles come from these in August and September, and are dark brown in color, cylindrical and one-tenth of an inch long. They are rarely numerous enough to do harm. Washing the trees with soft soap in August would tend to drive them off.

THE PEAR-LEAF MINER.

T. B. S., Ohio.—Inclosed I send the leaves of a pear tree which have black specks upon them, and after a while the leaves fall off. Can anything be done to prevent this?

ANS.—The leaves sent are injured by a small insect which eats away the soft portion of the leaf, leaving the firm skin, or epidermis, as a tough, colorless layer. These insects are not considered a serious pest to the pear, and probably nothing need be done to destroy them. If, however, they are numerous it may be well to try some one of the several insecticides.

Miscellaneous.

J. L. H., Spring City, Tenn.—What early variety of potato would be likely to succeed in this latitude?

ANS.—We would ask our friend to examine the Potato Special of the R. N.-Y. which will be published before the new year.

T. H R., Perry, N. Y.—Please tell where in New York city a reliable commercial

bulletin is published and the subscription price for a bi-weekly.

ANS.—Commercial Enquirer, $2.00; Commercial News, $5.00; Commercial Gazette, $2.00; all weeklies. One of these should fill the bill.

S. A. L., Malcom, N. Y.—I inclose a spray from a vine, the seed of which came with the first or second of the RURAL'S seed distributions. It is nearly hardy, grows from 10 to 20 feet in a season, but, sometimes is killed back in the winter. Will you tell me what it is?

ANS.—The vine is Vitis heterophylla variegata. It is also called Ampelopsis by some botanists.

R. C. F., Sinclairsville, N. Y.—A neighbor of mine proposes to cut oats in the straw, with his corn in filling his silo; what will be the result? He proposes to save thrasher's and miller's bills?

ANS.—As we understand it, the oats are now ready to thrash. If this is so, we do not see what will be gained by putting them in the silo. They might be fed as they are, forked to stock like hay. Many farmers do this and save thrashing. Thus fed, if the straw is bright and well cured, the oats would make an excellent dry ration to go with the silage.

Discussion.

FEEDING HOTEL SWILL SLOPS.

H. A. W., JAMESTOWN, N. Y.—Several years ago a neighbor had 18 sows from which he intended to breed. They were White Suffolk and Chester-White grades. One seldom finds a finer, more symmetrical and thrifty herd, having been brought to five months old on sour milk, sweet apples and a clover-and-grass range. When cold weather set in, this farmer commenced feeding, in addition to milk and apples, meat scraps and swill obtained at a fat-rendering and swill-gathering plant. This many times emitted an odor so offensive that complaint was made that his swill cart was a nuisance, as it was driven along the road. These shoats continued to thrive and fatten on this feed during the cold winter weather. When the days began to grow warm in spring and the sows farrowed, the pigs invariably came weakly, and remained so until about a week or two old when they died off rapidly without any apparent disease, and soon the mothers sickened and died, until all but three of the entire herd—mothers and pigs—were dead. There was no perceptible disease marked by looseness of bowels or loss of appetite, etc., but in several cases the sows would sicken at the trough while eating and die inside of 24 hours. This same man had five shoats that he had fattened for the butchers on this kind of feed with the addition of a small quantity of ground oats, and after the death of his herd in this way became known, he could not sell them to any butcher; so he butchered them himself and sent the carcasses to New York where they were sold. Another neighbor living near this place had a herd of 42 as fine Byfields and Chester-Whites as a man could look upon. He kept two boys who gathered hotel and private swill slops every day. His hogs had a range of about four acres, and appeared to do well for about three months, after which, as soon as hot weather set in, they began to sicken and die. He lost 16 of his best when I saw them, and bought two four-months-old shoats (sows) for breeding. I advised cooking the food and feeding plenty of sulphur and salt. The death rate decreased from that time until the trouble was completely arrested after he had lost 20 of his best and heaviest hogs. He had also a large flock of fowls—ducks and turkeys—which were fed upon this swill with a mixture of a few screenings. These had, at first, looseness of the bowels; their wings drooped and after a day or two they died, being often found under the roost dead, having died during the night. One thing was remarkable—he told me that from the eggs set for hatching not one healthy chick or duck was ever raised after the hens and ducks began to feed upon this refuse. When he commenced cooking this food, he was aware of a change in the condition of his hogs and fowls. There are two men who gather swill in our town, and they never use it until it has been thoroughly cooked and never see any bad results when it is thus fed. It's a fact beyond contradiction that the more wholesome the food, the less disease can be carried with it, and the better will be the result and the more wholesome the meat for food. The hog, although a hog, is decidedly particular in regard to cleanliness as to food and keep. He wallows in the mud to protect himself from flies and vermin; but naturally he is adverse to filth and revels in wholesome food and cleanly quarters as well as in a change of diet.

PASTURING MEADOWS.

F. E. E., GENEVA, N. Y.—During a recent short trip in Canada the practice of pasturing fields, and especially the wheat fields newly seeded to clover, was very noticeable. Here were herds of cattle, sheep and swine, turned into the fields apparently as soon as well cleared of grain. In some cases the new growth was short and apparently grazed off perilously near the roots. The exceptions to this practice along the railroads on which I traveled were comparatively rare. The practice was particularly noticeable to a resident of New York where so much has been said in the agricultural press against it. After noting the custom, the discussion in the last RURAL on this subject becomes more interesting if possible. It is probable that for any particular reason, the best method of practice has been put into use by the solid common sense of the community, and that while our Canadian neighbors may have found this plan profitable, it may be the least desirable way to treat a freshly-seeded field in some portions of New York, as well stated in several papers in the RURAL'S discussion. The condition of the fields and the amount of herbage, as well as the length of time they are pastured, the moisture of the soil, etc., are the most important factors in the case. The good judgment of the farmer, reinforced by his knowledge of the best treatment of his fields, should determine when the conditions are likely to make it profitable for him to pasture his meadows or newly-seeded ground. Nearly two years ago at a farmers' institute, in Ithaca, after a full and free discussion, the sense of the institute was taken by votes, with a special reference to pasturing off by sheep. It was agreed by a large majority that where the pasturing is not too close, if the sheep or other animals are removed early enough to let a late growth start up for winter protection, no harm would result from the pasturing. This Canadian practice is likewise the practice of very many of our own best farmers, as recent issues of leading agricultural papers abundantly prove. That the interdependence of vital conditions and the practitioner's knowledge and judgment sometimes gets out of balance, and harm is done cannot be doubted. The numerous reported instances of injury of this kind, appear to me to have been responsible for the outcry against the practice. There are fields in New York which have been mown and on which the aftermath has been grazed off for more than a score of years in succession, which are (or were two years ago—the writer has no word from them since) yielding good crops of hay annually. Good judgment is used in feeding off the aftermath and occasionally each field gets a top-dressing of good manure. These notes are hardly needed in the RURAL'S symposium, to show that grazing the aftermath from our fields need not necessarily be a cause of decay or an indication of future short crops.

THE BORDEAUX MIXTURE AGAIN.

L. E. A., SMYRNA, DEL.—I have been experimenting with the Bordeaux Mixture on my grapes this season to prevent the rot. I made five applications—on May 21, June 3, June 24, July 3 and July 15. This has been a very wet season and I had to make the applications between showers. Sometimes rain fell before I could finish spraying. From what I have noticed this season, all applications ought to be made as near the first and middle of the month as possible. We had two periods of rot; the first was about June 3, the second July 10. The mixture should be put on in large quantities. The fruit and foliage should be covered after the grapes commence to rot. I have 1,400 vines and in the five applications I used 260 pounds of sulphate of copper. The formula was six pounds of sulphate and six pounds of lime to 22 gallons of water. A row of six Moore's Early vines not sprayed bore 2.7 pounds of fruit. The rows on either side of this unsprayed row bore, respectively, 96 pounds and 112 pounds of grapes and the fruit was poor on the row not sprayed. One-half of a row of Agawams was sprayed, the other half was not: the foliage on the half that was sprayed is as green as can be; that on the half not sprayed, is off, (September 6) and has been for two weeks. The fruit on the unsprayed half will not be ripe for some time; the fruit on the half that was sprayed was shipped August 31. To remove the mixture from the fruit after the latter is ripe, take one quart of vinegar to five gallons of water; let the fruit remain in this mixture about three minutes; take it out and rinse it in clear water. Then spread it in the sun to dry. Last year I did not use the Bordeaux Mixture and I shipped 240 pounds of grapes; this season I had 3,100 pounds. I do not consider mine a fair test, as the season has been so wet. In washing the fruit, I had a light iron frame made about the size of a cheese box; I covered it with fine wire netting and washed half a bushel of grapes at a time. I also sprayed my pear trees to kill the slug. The formula was: half a pound of white hellebore to 40 gallons of water. It was quite effective. I also used the same with good success on gooseberries to kill the worms.

WHAT IS THE INFLUENCE OF MUCH BARNYARD MANURE UPON POTATOES?

BYRON D. HALSTED, RUTGERS COLLEGE.—At the recent meeting of the Middlesex County (N. J.) Agricultural Board there was a good deal said upon the subject of the conditions favorable or otherwise to the potato rot—a trouble that has seriously injured the potato crop in the county, and therefore shortened the income of many farmers who rely upon this crop as their principal source of revenue. In the discussion the prevailing opinion seemed to be that a large amount of barnyard manure added to the soil just before planting was conducive to the rot. It is easy to see that this might be the case. The rot is due to the growth of a minute fungus that sends its small threads through the substances of the potato plant. It is a form of vegetation belonging to the same group as the mushroom, toadstool, puff-ball, etc., only very much smaller. However, the portion of the mushroom that is below ground consists of fine filaments, and in this it is not so very unlike the potato rot. It is well known that the conditions enjoyed by the mushroom are an abundance of decaying horse manure kept from becoming too wet by being mixed with sand or earth. While it is true that the potato rot plant does not feed upon the organic matter in the soil in the manner observed by the mushroom, it is easy to see that the conditions of heat and porosity of the soil, etc., may be such as to favor the inoculation of the tubers and the development of the fungus when it is once within the potato. It seems to me that now while we are in the midst of the harvest of the crop at the close of a season where rot has been prevalent, it would be well to have a short report from a large number of potato growers upon the soil conditions favoring the rot, with especial reference to the influence of manure upon the disease. It may be, from the fact that the potato tuber is subject to scab, wire-worms, etc., that it, above all other crops, is best adapted to a diet of commercial fertilizer. What is the experience of the potato growers among the RURAL readers during the present wet season?

LEAF-BLIGHT AND CRACKING OF THE PEAR.

E. A. S., WASHINGTON, D. C.—In addition to what is stated in Prof. Halsted's interesting article in a late RURAL, I would like to say that experiments made by special agents of the Department of Agriculture during the present season have fully established that this disease may be prevented even more readily than the black rot of the grape. A circular has recently been issued by Mr. B. T. Galloway, Chief of the Section of Vegetable Pathology, giving a full account of some experiments carried on under his direction at the nursery of Franklin Davis & Co., between Baltimore and this city:—50,000 young trees were treated with the Bordeaux Mixture, the first spraying being made June 5, this being followed by four others at intervals of 10 days. The labor was done by one man and the cost of the chemicals used was about two cents per tree. The results were that while large trees which were untreated lost nearly all their leaves from the disease, the seedlings, which are even more subject to it than full-grown trees, were in excellent condition at last report—August 11th. The results of the experiment are confirmed by another made by Col. Pearson at Vineland, N. J. Two 10-year-old Clairgeau trees, which had been attacked by the leaf-blight year after year, were sprayed six times during the season with the Bordeaux Mixture, and a third standing near the others was left unsprayed. On August 22nd, the two treated trees were in full foliage, while the untreated one had lost nearly every leaf, a photograph taken at that time showing scarcely more than a dozen. Prof. Halsted's encouraging words have thus been more than realized, and pear-growers may confidently expect to conquer this very troublesome and hitherto dangerous enemy.

THE MONTANA BOOM!

CHAS. A. GREEN, ROCHESTER, N. Y.—On my recent return from the Pacific coast, via the Northern Pacific Railroad, I passed entirely across Montana. To me, accustomed to the luxurious and leafy East, Montana looked like one vast desert. I considered it the least promising of all the States and Territories, yet I saw nothing except the land and towns along the railroad.

I noticed one large and one small grave near a forsaken home. A man, wife and child located bravely in this desolate spot, with hopes of prosperity. The wife, removed from friends and neighbors, schools and churches, became homesick and weary of life and died. The child soon followed her, and the father, heartbroken departed, no one knows whither.

How often this story is repeated throughout the great West. People who go there to settle know nothing of the country. They are not able to go and see it before moving. They stake all on the venture, taking a leap into the dark. I have known Eastern women so homesick in their new homes in the West, they would weep for hours daily until their grief preyed upon their health, and they became invalids. Many a man has been compelled to return East on account of his wife, who could not live there. It was simply die or get home, and they went home if they had money enough to get there, which is often lacking. If men desire to go West let them go before they get married.

[Let us hear from others who from actual experience can speak of Montana—others, besides the syndicate of editors of farm papers who have land for sale and are selling it through their columns both editorial and advertising. Let us hear from men who will tell us the truth. Eds. R. N.-Y.]

ROT IN POTATO "SEED."

D. C. L., CRANBURY, N. J.—We are told on page 612 of the RURAL, that the scientists believe that the spores or germs of the potato rot remain in the tubers for a considerable time. On Monday last I attended a meeting of the County Board of Agriculture at New Brunswick. We were addressed by Prof. Austin, of the New Jersey Experiment Station, on this very subject. He coincides with what was said in the RURAL. Now, it may be desirable to look up localities where rot has not appeared, in order to secure seed from such places for next year. Two years since I had eight acres planted to potatoes. About one acre of the eight, owing to excessive rains, rotted. The trouble was confined to the flats from which the water could not pass off in time. The potatoes rotted entirely on all such places; while on rising ground there was no rot whatever. I planted the potatoes from the latter the following year and had no rot, although I have lost 700 or 800 bushels by rot this year. The trouble is again confined to the lower parts of the field, as before, and there is very little, if any, rot on the higher parts. I expect to plant some of this year's seed next year, and I shall expect as favorable results as I obtained from the seed secured from the drier regions of that year's products, unless the conditions—as they have been this year—are favorable to rot from excess of moisture and high humidity. I would like to hear from others on this subject.

IN FAVOR OF CREAMERS.

C. H. E., AVOCA, N. Y.—Allow me to offer a few suggestions to W. E. R., Dover, N. H. A few years since a creamery was started here on the cream-gathering plan, and after making several tests with a view of selling cream, I gained some information that rather surprised me. I mixed the milk from all of the cows together, and took 100 pounds and set it in shallow pans—the old way—and let it sour before skimming, and 100 pounds were put in creamery cans which had tubes in the middle for the water to pass through, and they were set in water kept not above 50 degrees. The milk in the creamery gave the most cream, and one-fifth more butter than the other. My experiments proved to me that, as many have claimed of late, "cream is not cream;" for whereas most of the patrons claimed they could not make any more butter than the gauges called for, yet mine always overran from three to four pounds on 10 gauges of cream. I am now using the Channel cans and set them in a tank of water with ice, and make my own butter, as I could not afford to sell the cream by the gauge. After the milk has been set 12 hours, and a scum has formed, no more cream will rise if it is left ever so long, and there is much less work in taking care of milk in a creamery than in pans, and the cream is never over-ripe.

'WHENCE COMES THE COLOR OF BUTTER?"

O. K. L., INDIANOLA, ILL.—"Whence comes the color of butter?"—page 558 of the RURAL. Fowls fed on white corn will produce an egg with a pale-yellow yelk; if fed on yellow corn the yelks of their eggs, when boiled, have a deep orange tint. Again, I've taken fish from the head of the lake where the bottom is sandy, and such fish are of a light shade, while fish of the same species taken from the foot of the lake, where the bottom is of black mud, are very dark-colored. Some contend that the stomachs of animals are "perfect strainers," and that all coloring and foul matters pass off in the voidings, and that the flesh or milk. ètc., are pure. Not so. Chicken meat, beef, and milk taste of garlic; milk of ragweed, etc., when the animals which produce them have fed on these substances Some hog raisers feed refuse from starch factories, stinking ground corn, and bacon from hogs fed on such stuff will, when cooked, drive a black dog from home. If stench from feed is transmitted to milk and meat, why should not coloring material? I believe that milk and butter from cows drinking stagnant water are not healthful.

CAUSTICALLY IN FAVOR OF BUTTER COLORS.

F. H., CRANFORD, N. J.—W. P. W. on page 561, of the RURAL is evidently trying to make a point against butter color, but only succeeds in displaying his own ignorance. He says there is no demand anywhere for annatto-colored butter and cheese, and that the demand is wholly confined to the producers and sellers. Did any one ever hear of the demand for an article originating with the producer? According to all laws of trade, the demand must come from the consumers. The demand is for yellow butter; very few consumers will purchase any other; the dealer will not purchase what he cannot sell; the producer will produce what he can sell to the best advantage; he cannot sell white butter to advantage, hence he colors it. Farther than this, if he depend on the cow to color it, she will not do it uniformly with the varying feed of different seasons, and fancy butter must be of uniform color. Who is deceived? No one, and any one writing such bosh as does W. P. W. proclaims himself either a crank or an ignoramus.

ALLITERATIVE ARTICLE BORN OF BRAINS.

P. B. C., CATONSVILLE, MD.—Cows cost considerable but declare dividends; if they eat enormously and are fed faithfully they will give great gains. Handle heavy horses and invest intelligently. Juvenile jumpings and kickings kill with kindness. Land likes much manure, needs nitrogen and ofttimes oxygen. Pigs pay profitably; but, quite queerly, "runts" ruin results, but read the RURAL and success is sure; for tried truths are told usefully and understandingly, and various vagaries which want wisdom are explained excellently, yet it has yet to reach its zenith.

AN ADVERTISEMENT CORRECTED.

T. B. TERRY, HUDSON, O.—That is too bad for Hoover & Prout that you should say in their advertisement that "I dug 100 bushels last week." It was 1,000 bushels, and we had only been feeling of the job at odd spells. When we got warmed up to business, my son and I and three pickers dug and put in the barn 400 bushels in one day. The next day my son was gone to school, but we got in 350 bushels, thanks to machinery, clean culture, our potato boxes, system, etc., etc.,

W. O. F., GREENSBURG, INDIANA.—In a late RURAL we are told: "There have been 50 failures of wool dealers in the last six months. * * * The great depression in the wool business is uniformly attributed to the present high tariff on the raw staple and a combined effort is to be made, at the next session of Congress, for a great reduction, or the entire abolition of the import duties on wool. The National Association of Wool Manufacturers has called an extraordinary meeting of that body at Boston on September 17, for the purpose of taking vigorous action in the matter. Isn't it time for the wool-growers of the country also to take prompt and vigorous measures to counteract a growing agitation which seriously threatens their interests?"

There are 65,000,000 people in this country and some 43,000,000 sheep. Probably 100,000, all told, men, women and children are benefited by a tariff on wool; the other 64,900,000 would be benefited by the entire abolition of the duties on both the raw material and manufactured product. From this view of the matter is it not high time that the people generally—the farmers especially—should take vigorous action to have these duties repealed so as to give us free clothes and free wool?

R. N.-Y. At the usual basis of five to a family, 100,000 men, women and children would represent 20,000 families, or farms. The census of 1880 shows that sheep were kept, in that year, in 2,460 counties in this country. If there were only 20,000 farms on which sheep were kept the average was not five to a county—a manifestly absurd statement, when we realize that there were in 1880 4,008,907 farms in this country.

H. G. L., CHARLTON, MASS.—As my eye catches the comment upon the Kieffer Pear on page 589, I am almost fierce with rage. Such attempts as have been made to push the little, insignificant, hide-bound thing to the front tend greatly to chagrin dupes. Yes, the tree grows well enough, but such fruit is not worthy of decent comparison with good sorts.

E. B. T., AMENIA, N. Y.—I use milk freely in mixing feed for chicks and value it highly. I *never* give it as drink, as I beleive more than a little of it to be injuriou

What Others Say.

ECONOMY IN THE PURCHASE AND USE OF FERTILIZERS.

To the consumers of commercial fertilizers Prof. George H. Cook tells us, in a late bulletin, a knowledge of the sources of supply, the cost and chemical composition of unmixed fertilizing materials is important from two standpoints: 1. Economy in buying. 2. Rational use.

ECONOMY IN BUYING: Statistics secured by the New Jersey Station, and published in the annual report for 1888, showed that the average composition of mixed or complete fertilizers analyzed during that year was 2.77 per cent. nitrogen; 8.09 per cent. available phosphoric acid; 2.82 per cent. insoluble phosphoric acid, and 4.29 per cent. potash, and that the average selling price was $34.83 per ton; in other words, the nitrogen cost on an average 21 cents per pound; available phosphoric acid 10.2 cents, insoluble phosphoric acid 3.8 cents, and potash 5.4 cents. The same amount and kind of plant-food could have been bought that year at the factory, unmixed, and for cash, at an average price of $27.42 per ton. *The average charge for mixing, freighting and selling was therefore $7.41 per ton.* In Bulletin 98 of the Connecticut Experiment Station, containing the analysis and valuation of 11 samples of home-mixed fertilizers, it is shown "that at the *regular cash ton prices of the trade*, and including freight charges and cost of mixing, the average cost of home-mixed fertilizers was, *at the highest estimate*, $35.79, and the average valuation $38.83 per ton; that in no case was the valuation less than the cost of chemicals mixed; and further, that from such raw materials as are in their markets, without the aid of milling machinery, mixtures can be and *are* annually made on the farm, which are uniform in quality, fine and dry, and equal in all respects to the best ready-made fertilizers." This work of the Connecticut Station not only confirms the New Jersey Station's results as to the saving effected by buying unmixed materials, but also shows that the raw materials can be secured of such good mechanical condition as to render it entirely within the power of the farmer, with ordinary appliances, to make an excellent fertilizer.

RATIONAL USE.—While it is a fact that nitrogen, phosphoric acid and potash are in most cases the only chemical constituents necessary to add to any soil to prevent ultimate exhaustion by continual cropping, the knowledge of that fact becomes profitable largely in proportion as it is modified by the individual farmer so as to conform to his soil and his crops.

It happens too frequently that the increase in crop from the use of complete manures is produced by one or two only of the elements present. When, as is often the case, nitrogen is either inactive or produces an abnormal effect from the presence of insufficient quantities of phosphoric acid and potash, and immediate returns are unsatisfactory, future gains are also problematic, since nitrogen in readily available forms is easily movable in the soil, and eventually lost. Phosphoric acid and potash, on the other hand, if inactive for immediate crops, are retained in the soil, and serve for future crops.

~tatistics in regard to the composition and cost of complete manures in 1888 showed that the average cost of the nitrogen contained in them was just one-third of their total cost. In the use of fertilizing materials, and especially of this most expensive element, *nitrogen*, great care should be exercised; and the use of unmixed materials, for studying the various soils and crops, is particularly advised.

PROF. RILEY'S WORK IN THE PARIS EXPOSITION.—The London (England) Post speaking of our department in the Paris Exposition says that in the section of applied entomology, as might have been expected, since it is Professor Riley's specialty, the exhibit as a whole far excels anything else of the kind in the exhibition. There is a large and varied display of appliances for bee culture, and for the preparation and marketing of honey. In no other country of the world are so many persons engaged in honey producing, and nowhere else is so much honey produced at so low a cost. The many forms of hives, of honey extractors, foundation comb presses, and other contrivances for facilitating the management of bees and the marketing of their products, all show that our American cousins are foremost in the application of inventive genius to this branch of rural industry. No less than 18 different patented forms of bee-hives are shown, besides a comprehensive series of different honeys in the comb and in various sealed packages. One large case is devoted to these honeys, those from Lime Blossom, White Clover, Sage and Mangrove being particularly noticeable for their excellent quality. Wax extractors, bee smokers, various forms of honey confectionery, and even honey wine and honey vinegar are all to be seen here. It is estimated that in the United States there is a total of 3,000,000 colonies of bees, annually yielding 120,000,000 pounds of honey. The value of this annual product, at an average price of 15 cents per pound, would be £3,600,000 sterling. The estimated annual product ranges from £3,000,000 to £4,000,000 in value, and the annual production of wax is calculated to be worth £200,000.

WORTH NOTING.

LIVINGSTON'S GOLDEN QUEEN is the best yellow tomato as yet tried at the Rural Grounds. The tomatoes are large, generally smooth, firm and of mild quality. They ripen thoroughly and evenly in midseason. The vines are abundantly prolific.

HORSFORD'S PRELUDE is in all ways, except one, a valuable variety. The one objection is its size. The tomatoes ripen with the earliest. They are free from rot, round, bright-red in color and bear abundantly during the entire season. Those who value a very early tomato should try the Prelude.

THE IGNOTUM is about all that has been claimed for it—very large and firm. It is medium to ripen and bears a great quantity. It should be grown for two or three seasons longer from careful selections ere it be put on the market.....

SECRETARY E. WILLIAMS, of Montclair, N. J., has for years made a study of pears. In a late number of Garden and Forest he presents his views respecting a number of the later pears which, as the season of transplanting draws near, may serve to guide our readers. Belle Lucrative, he says, is a pear of medium size and excellent quality when well-grown. It is an abundant bearer, and, if allowed to do so, will overbear, to the detriment of the fruit, both in size and quality. The skin of the fruit is an unattractive green, and for this reason, among better looking pears, it is apt to be passed without notice; but its buttery, juicy flesh amply compensates for any lack of good looks. Golden Beurré is of medium size, and in appearance directly opposite of the preceding, while approaching it in quality. This immediately follows the Bartlett. ....

LOUISE BONNE has of late years developed the fault of shedding its leaves so early that the fruit is never fully grown.....

MR. WILLIAMS speaks of the Buffum as a pear of medium size, fair quality and one of the most healthy, vigorous growers in the whole list, and an abundant bearer every other year. Sometimes the fruit is rather under-sized from over-bearing, a tendency in all pears, and some years, too, it is less juicy than in others. It is then excellent for cooking. With approaching ripeness it assumes a yellow and handsome appearance..

BOSC is a long, slender-necked russet pear, of the highest excellence, sweet and rich. The tree is a poor, open grower while young, and the fruit is borne singly or in pairs generally, and very evenly distributed. It is most satisfactory when top-grafted. This was Mr. Downing's favorite pear, and his judgment on this point seems eminently sound.....

SHELDON, a round, russet pear of medium to large size, flesh granular, melting, sweet, juicy and aromatic, is a fruit of the highest excellence. The tree is a lusty grower and generally productive. It should be in the smallest collection.....

URBANISTE is another large pear, in quality equal to any named; skin, smooth, greenish-yellow; flesh, melting, buttery, rich and juicy. The tree is a fair grower, but is not popular among dealers and planters because, like the Tyson and some others, it is tardy in coming into fruit. The old adage about planting pears for one's heirs, is not regarded with favor by tree-planters now-a-days; they are in a hurry, and would like the trees to commence bearing at once. When one has old trees of undesirable kinds, a new head of Urbaniste could be grafted on and this excellent variety would soon come into fruit.....

WINTER NELIS is a small russet pear of excellent quality when well grown, but the tree generally loses its foliage early before the pears mature, and, therefore, they seldom reach perfection. The tree is a slow, slender grower, and should be top-grafted on some more vigorous kind.....

DANA'S HOVEY is among winter pears what the Seckel is among autumn varieties. The tree is a good, healthy grower, and produces fruit about the size of the Seckel, but better and more highly flavored. If it were only a little larger!.....

LAWRENCE is an American pear of great excellence. The tree is of moderate growth, very healthy and productive; the fruit of medium size, smooth, yellow at maturity when grown on young trees, but on old trees it is very apt to become cloudy or rusty. The skin is thick, flesh fine-grained, buttery, sweet and juicy, and it will keep till Christmas with ordinary care.

THE R. N.-Y. if it were again planting a pear orchard would select the following for home use in preference to any others of their season: Buffum, Sheldon, Anjou, Seckel and Dana's Hovey .....

MR. WILLIAMS regards the Kieffer as a valuable substitute for the quince, and, as it will produce fruit far more abundantly and cheaply, it is well worth planting for its excellence in taste and appearance when preserved .....

A. W. CHEEVER, of the New England Farmer, recalls several young men of his acquaintance who put their first money into horse flesh and pleasure carriages, but he does not recall any who have made a marked success in life who began in that way. The young man who makes himself indispensable to his employer doesn't have much time for riding over the country outside of service hours. The young man who complains that his work is monotonous or confining during the entire years of service is not the one to find himself in specially easy circumstances later in life.....

THE GREEN MOUNTAIN is probably the earliest hardy white grape of excellent quality known to-day.....

PROF. BUDD, of Ames, Iowa, speaks of a Russian Almond that is as hardy as an ironclad apple.....

DR. NILES and Dr. Bolton of the South Carolina Experiment Station have been investigating hog cholera without throwing any new light upon the subject. They remark that as in typhoid fever, and other diseases in man, all that should be attempted is to assist the natural forces of the animal in overcoming the disease. Any drug administered for any other purpose than this can do no good, and may do harm. The administration of all sorts of drugs recommended is enough of itself to kill the animal in many cases, and the practice cannot be too severely condemned. Some cases where the animal is particularly vigorous, or where the disease is of a mild type, recover of themselves, and it is probable that remedies which have gained popularity have done so by having been tried upon such cases, where the recovery would take place without any treatment. There are so few cases of recovery in some outbreaks, and the difficulties of treatment are so great that it is not advisable to try any remedies at all....

PROF. E. M. SHELTON says, in a late bulletin, that salt does not enter into the composition of plants as a necessary element: that is, plants may be grown and brought to perfection in soil which contains none or only a very small proportion of this mineral. If salt then is beneficial to a crop, it must be due to the fact that it acts upon the necessary elements of plant-growth by

which these are made more available to the plants. Some 10 years ago the R. N.-Y. experimented with different quantities of salt on wheat. In no case did it increase the yield. This, however, was within two miles of the ocean.....

HENRY STEWART reminds readers of the N. Y. Times that a mistake is often made in the use of hot water in cleaning dairy utensils. Hot water makes milk curd insoluble and hard and tough, so that when utensils are scalded before they are thoroughly cleaned from the remains of sour milk, the curd is solidified in the pores of the wood and becomes a permanent agent of mischief. Any alkali dissolves curd of milk, and after first well rinsing the utensils, and especially the churn, with cold water, a solution of common soda or saleratus (carbonate of potash) may be very usefully employed to complete the removal of all traces of the sour milk. Then another rinsing with cold water, followed by a scalding with boiling water and a finishing dashing of cold water, always pure, will complete the work. The washed utensils should then be placed under an open shed in the free air or in a clean, airy, dry dairy for use again.....

IN the American exhibit at the World's Exposition in Paris, is oil made from the germ of corn. Florida has a "strong alcoholic cordial made from oranges." There are 400 specimens of grass prepared by Mr. Vasey the United States Botanist.....

EARLY RED CLAWSON is advertised as the earliest variety of wheat in circulation...

JONES'S WINTER FIFE is advertised as being for the winter-wheat sections what Spring Fife is to the Northwest.....

GOLDEN CROSS is highly prized where it has been tried in Central New York.....

NOW FOR hardy bulbs. Prices are lower than ever before, and a bed of hyacinths and tulips, so refreshing and beautiful in early spring, may be secured at a small cost.....

THE AMERICAN FARMER advises its readers to raise everything they can to supply their table and family wants. When a farmer has to buy an article which he can produce on his farm, you can just put it down that that man has "missed his calling." With but few exceptions farmers can make themselves independent of "corners" on articles of food, and it should be the aim of every farmer to make his business self-sustaining to the best of his ability.....

PROF. A. J. COOK gives an experience, in Gleanings in Bee-culture, showing the carelessness with which many statistics are gathered. A report from the Department of Agriculture stated that the chinch bug had done serious damage in five counties in Michigan. Prof. Cook did not believe this was true, as in all his collecting he had never taken a chinch bug in the State. So he wrote to the Department and learned the names of the reporters, and immediately addressed a letter to each one as follows: "Do you know the chinch bug? Do you personally know that it has ever worked in your county? Why did you report ravages from this insect in your county to the Department of Agriculture?" Answers were received from three persons only. They reported that they did not know the insect, that they had no personal knowledge on the subject, and did not know that they had so reported. What are statistics worth if we are to have such reports?.....

BURYING GRAPE VINES IN WISCONSIN.—Bulletin No. 17 of the Wisconsin Station, issued in 1888, contained an excellent article on Wisconsin grape growing by Prof. W. A. Henry. After giving some strong arguments in favor of growing grapes in Wisconsin, Prof. Henry proceeds to give a list of the most suitable varieties, the portions of the State where the industry is most promising, and hints concerning the cultivation and care of the vines. The pictures given in this bulletin were of unusually good quality. The R. N.-Y. copies the one that is most timely at this season. It is engraved from a photograph taken in the vineyard of the Wisconsin Station, and shows just how the workmen proceed to prepare the vines for winter. This is what Prof. Henry has to say about it:

"BURYING THE VINES.—Here is another point greatly misunderstood by many. Our people have mostly immigrated from a milder climate than this and are not accustomed to burying plants to protect them from the rigors of winter. As well let cattle go unhoused in winter as grape vines unburied. Both may possibly survive, but at entirely too great a cost. Nor is the labor of properly protecting them great as will be shown further on. In order to make this matter plain, we present an illustration of a scene in our vineyard this fall when we were closing up the vineyard work See Figure 244. A trimmed vine temporarily tied to a post is shown on the left. Another trimmed vine is bent over, a man standing with his foot upon the top while an assistant throws a few spadefuls of earth upon it. The foot is then removed and both men continue the covering until the vine is buried just out of sight. The object of covering is not to keep the vine from frost, but rather to keep it frozen all winter. It is the alternate freezing and thawing, not steady cold that injures the vine. Bear this in mind and do not cover deep.

UNCOVERING THE VINES.—Before the buds start, but as late as possible, uncover the vines by gently lifting them out of the earth that encases them with a four-tined fork. The work is rapidly performed. It required a total of 15 hours' work for burying something like 168 vines, while only six hours were required for uncovering. The earth heaped up in covering the vines is leveled again with the first cultivation."

BURYING GRAPE VINES IN WISCONSIN. FIG. 244.

WORD FOR WORD.

—THE CENTURY MAGAZINE: "The wages of righteousness are earned by the job, not by the day."

"You may pull the ox out of the mire on the Sabbath day, but don't push him into the mire for the purpose of pulling him out."

"Blue blood should assert itself without the help of a placard."

"Life is a half-way house, and each guest should take contentedly the room to which he is assigned."

"The back-log without the small sticks will never heat the room."

——BREEDER'S GAZETTE: "No; the demand for Dr. Brown-Sequard's alleged "elixir of life" is not likely to affect the market for lusty buck lambs to an extent justifying sheep-owners in making any very extended preparations for furnishing on a grand scale the raw material for rejuvenating the lame, the halt, and the blind."

"BEYOND any question the hogs inoculated by Dr. Billings were cholera-proof."

——LIFE: "A cut-and-dried affair—A load of hay."

——ORCHARD AND GARDEN: "Pres. Lyon in the RURAL NEW-YORKER, pronounces the Erie and Lawton Blackberries *not* alike. The Editor of the R. N.-Y., considers the Erie a hardier variety. We have grown these varieties for some time and noted them carefully. While there is a similarity in habit of growth and also in fruit, a careful comparison will show them to be distinct. In season of ripening the Erie is much earlier than the Lawton, the canes are more vigorous in growth and very much hardier."

——ELI MINCH: "J. H. Hale of South Glastonbury, Conn., is reported in the RURAL NEW-YORKER to have the promise of a large peach crop which he claims to be the result of the use of 400 pounds annually of muriate of potash and a liberal use of bone dust. We find the same results in our case. We prefer kainit and bone, as the kainit contains so much salt which for the peach is a good restorative of unhealthy trees. This fact is emphasized in a marked manner by the unusual health and vigor of all peach trees that grow near the edge of salt marshes. Those nearest to the marshes are always the most vigorous."

——WEEKLY PRESS: "When a milk producer has been requested a few times by his dealer in the city to take some of that 'yellow stuff' off his milk before he ships it, he is very apt to do so. It seems to be a fact that a large amount of cream in milk is not, as a rule, appreciated by the city dealer or his customers. Certainly the farmer receives no extra compensation for it. This being the case, the Holstein or Ayrshire is a better cow for the milk producer than the Jersey, and is properly valued according to the amount she gives, and not for the number of cream spaces her milk shows."

——PROF. E. M. SHELTON, "Almost certainly the assessors' returns for another year will show a very large increase in the area of wheat sown the present fall in Kansas. All this seems to me a good deal unfortunate. Wheat is undoubtedly, taking the years together, a very profitable crop in Kansas when grown in connection with other crops, and as a part of a system. It is equally true that to cultivate it as a specialty is to certainly invite all the disasters that resulted from the excessive wheat-raising of 13 years ago."

——LONDON POST: "The meat industry is represented at the Paris Exposition by several firms, who show packed and cured meats of various kinds which have all been successfully conveyed across the ocean—some having even traveled a distance of over 5,000 miles—by means of refrigerator cars upon American railways, and by cold storage upon Transatlantic steamers.

The American meats are kept in a large and admirably-constructed refrigerator, made expressly for the United States Government by the well-known Chicago firm, Messrs. Wickes & Company. This refrigerator, which has no parallel in the Exhibition, has been much admired by visitors, and it is a pity that it is not illuminated from within, a defect which arises from some difficulties between the Exhibition authorities and the electric light companies, which the United States Commission has been unable to overcome. In this same refrigerator may be seen the American dairy exhibits of butter and cheese. These are necessarily small, but they form a most representative collection, and it is, indeed doubtful whether so fine a collection of butters has ever been brought together before. Amongst them are the products of three of the best known American dairy farms, all in New England. These farm-made butters command a high price in the United States throughout the year. Besides these exceptional butters, there is a collection of butters made on the factory system, all of good quality, and well kept after crossing the ocean. The American cheeses are less striking in quality than the butters, yet they are well made, rich in flavor, and well cured. Even more instructive, perhaps, than the exhibits themselves are the photographs, maps, and charts, illustrating the types of animals and the methods of husbandry, and of slaughtering of animals which are so characteristic in their extent and economy of labor."

Miscellaneous Advertising.

Hood's Sarsaparilla 100 Doses One Dollar

It is Economy to buy Hood's Sarsaparilla, because it is the only medicine of which can truly be said: "100 Doses, One Dollar." It possesses peculiar strength and curative power, and effects cures where other preparations fail. Try it, and you will realize its merit. Sold by all druggists. Be sure to get Hood's Sarsaparilla.

NOTHING ON EARTH WILL MAKE HENS LAY LIKE SHERIDAN'S CONDITION POWDER

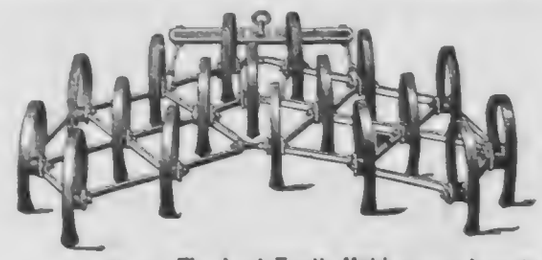
Highly concentrated. Dose small. In quantity costs less than one-tenth cent a day per hen. Prevents and cures all diseases. If you can't get it, we send by mail post-paid, One pack. 25c. Five $1. 2 1-4 lb. can $1.20; 6 cans $5. Express paid. Testimonials free. Send stamps or cash. Farmers' Poultry Guide (price 25c.) free with $1.00 orders or more. I. S. JOHNSON & CO., Boston, Mass.

HENCH & DROMGOLD'S

All Steel Frame Spring-tooth Harrow

A WONDERFUL IMPROVEMENT.

TEETH QUICKLY ADJUSTED BY ONLY LOOSENING ONE NUT.



The best Tooth Holder ever invented.

The tooth is held in position by a Ratchet with which it can be adjusted so as to wear from 15 to 18 inches off the point of the tooth, which is four or five times as much wear or service as can be obtained from any other Spring-tooth Harrow in existence.

Agents wanted. Catalogues free.

THE
RURAL NEW-YORKER,
(34 PARK ROW, NEW YORK),

A National Journal for Country and Suburban Homes.

Conducted by
ELBERT S. CARMAN.

SATURDAY, SEPTEMBER 28, 1889.

GREETING.

THE regular subscribers of the R. N.-Y. are both invited and requested to send in the names of any of their friends to whom they would care to have specimen copies of this journal mailed. Such lists of names may run all the way from one to 100. The specimens will be promptly forwarded all the same, and our best thanks will be due to those who favor us with such lists. It may be well to remind our later subscribers that the price of single copies of the R. N.-Y. is invariably $2 a year, while in clubs of five or over it is $1.50, the lowest wholesale price. Those who are willing to act as agents will find it easier to obtain subscriptions if those solicited to subscribe shall have previously improved the opportunity of examining specimen copies. The RURAL NEW-YORKER necessarily addresses itself to the more intelligent, progressive people of the country. It finds little comfort or profit in the ephemeral support of that class which is influenced more by a low price than by originality, enterprise and trustworthiness, in which respects, it will, perhaps, be generally conceded the R. N.-Y. is equaled by few other journals of its class.

THE Empire Co-operative Association, of 34 Reade Street, N. Y., has sued the RURAL NEW-YORKER for libel.

IS HAY, HAY? Is a ton of Timothy hay of the same value for feeding, regardless of the soil upon which it is grown?

READ what Dr. Halsted says about potato rot on page 643. We should be glad to hear from our readers on the subject. Read also the remarks of E. A. S. on the same page.

Last year I did not use the Bordeaux Mixture and I shipped 240 *pounds of grapes. This season I used it and had* 3,100 *pounds.* Read what L. E. A. says on this subject on page 643.

YES, let us hear from men who will tell us the truth about Montana—those whose eyes and judgment are not distorted by pecuniary interests. We caution our readers to beware of the flaming advertisements and laudatory editorials that are appearing in certain farm papers. *The editors* have land for sale! Read what C. A. Green says on page 643.

TRY an Eaton grape-vine, RURAL NEW-YORKER readers—if but one. Until the berries are dead-ripe, there is an acidity about them that may not please those who prefer very sweet grapes. When fully ripe, however, this acidity nearly disappears. The grapes being of the largest size without much pulp, give more juice than any other variety with which we are familiar.

THE R. N.-Y. has yet no less than 150 varieties of its hybrid and cross-bred wheats to plant. The soil is at present so soaked with water that planting would be inadvisable. Usually we aim to plant these wheats—'tis a tedious job—from the fifth to the 15th of September, beginning at the former and finishing at the latter date or thereabouts. As in years past, a single grain will be planted in the intersections of furrows made one foot apart each way.

MR. CROSBY'S remarks regarding corn and milk for poultry are suggestive. In sections where wheat is the most expensive grain why not feed, with corn, some substitute that will make the desired "perfect ration?" Mr. C. finds that milk provides what is needed. The chemists have made up certain rations for dairy cows, that practical dairymen have indorsed. Why not the same thing for poultry? The question is: If wheat is the best egg-producing food, will not a combination of substances, answering in chemical composition to the wheat, do as well as the grain? If this thing succeeds with a horse or cow, why not with a hen?

IN addition to the remarks on electricity found on page 642 we may give some comparative figures concerning the cost of various motive powers on our street railroads. When moved by horse power the cars average 60 miles per day, while the cable roads and the electric cars make 84 miles. The cost per day of a car drawn by horses is $5.91 or .098 of a cent per mile, the cost of a cable car is $7.47 per day or .089 of a cent per mile, while the cost of an electric car is $4.52 per day or .053 of a cent per mile. The original cost of the plant for an electric railroad is about twice that of a horse railroad; while it is shown that the cost, per mile, of running the electric cars is nearly half that of the horse cars.

A NEW YORK State subscriber proposes to conduct his business as follows:

"I am going to try a new departure, an account of which I never saw before: I shall label every bale of my hay, to show that it is all right. I believe that if farmers would sell their produce on a positive guarantee, they would get more money in the long run; for then the buyer would not be afraid to buy. I used to run a hay press myself and I know how some of the farmers cheat by their deception in pressing hay."

The R. N.-Y. feels sure that this plan will pay well. The conditions of the hay market are such this season that buyers will have the advantage. It is only the extra prime lots which customers can feel perfectly satisfied with, that will bring an extra price. The same principle of making oneself responsible for the article that one has to sell, is sure to pay in the long run.

"I believe in paint as a preventive of loose tires, but not in oil as a cure."—E. DAVENPORT, page 639.

IN the "Farrow vs. Fresh" discussion the authorities are practically unanimous in advising yearly calving. The R. N.-Y. is now experimenting in this matter with a Jersey cow.

The writer concludes from what little experience he has had that much depends upon the cow. Some animals after calving every year for a term of years will fall off in their milk-flow at the usual time, whether in calf or not. They may not entirely "dry up," but the milk-flow will be greatly diminished. Other cows will not fall off so much and will respond at once to an increase in feed. The R. N.-Y's. cow is of the latter class. She is now farrow. She has fallen off in her milk yield, but gives more than she did last year when in calf, and increases her yield when given extra feed. Still, she milks so closely up to the time of calving that the R. N.-Y. believes she will give more milk when "fresh" than when "farrow."

BY actual count, 153 persons have contributed articles or ideas to this one number of the R. N.-Y. There never yet was a farmers' institute held that presented such an array of "talent," and this is but one number out of 52, mind you. For the price of a year's subscription you get this number and 51 more just about as good as this is. There is one great point worth remembering. By means of our photo-engraving we are enabled to give our readers a peep directly into the houses, fields and barnyards of real farmers. You will not only hear what members of the Rural family have to say, but you will see the sort of houses they live in, the cattle and horses they like, the tools they use—in fact you will get a peep into their very lives. The R. N.-Y. is the only agricultural paper that can do this work. Are you surprised that our argument to would-be subscribers is: "Compare the R. N.-Y. with any other paper and then take the best?"

THE R. N.-Y. WOMEN'S POTATO CONTEST.

THE reports of those engaged in this contest must be received at this office on or before October 15th.

THE BOOBY PRIZE IN THE R.-N.-Y.'s WOMEN'S NATIONAL POTATO CONTEST.

THE wife of the Editor of the RURAL NEW-YORKER was one of the contestants, and the following is a summary of her report: One-fortieth of an acre of a thin, moist soil was selected. Plowed in August; 1,000 pounds of New York stable manure spread in September and spaded under; one barrel of unleached wood ashes (partly charcoal) spread in early March. Plot again spaded April 5; 40 pounds of Bowker's potato fertilizer sown before the trenches were dug. Trenches nine inches deep, a foot wide and three feet apart. Planted April 11 as follows:

Rural New-Yorker Seedling No. 2, 100 pieces; R. N.-Y. seedling No. 3, 50 pieces; R. N.-Y. No. 4, 100 pieces; Brownell's Winner 113 pieces, making 363 pieces in all.

The vines made a strong, healthy growth and the stems were in early July as large as any we have ever seen. The punctures of the Flea-beetle at this time began to blacken the leaves, and in a few days the vines were dead. An examination of several hills showed that most of the potatoes were a mass of decay. Here is the yield:

No. 2, 85 pounds; No. 3, five and one-quarter pounds; No. 4, 28½ pounds; Brownell's Winner, two pounds or 120¾ pounds in all, which is at the rate of 80½ bushels to the acre. This nearly total failure is attributed in great part to the fact that a moist plot was selected in anticipation of a dry season.

THE NEXT CENTURY.

FIFTY or 60 years ago statisticians gave figures indicating the future population of the United States. Most of the estimates were considered wild and visionary by ordinary people, yet the actual results have shown them to be surprisingly correct. If anything, the tendency of the computers was to put our population at less than it really proved to be. Just now, some of our ablest statisticians are making estimates as to our future population. The estimate that seems most generally considered worthy of attention is the following, made by Mr. M. C. Meigs, a man of ripe age, careful training and one who has had ample means for the investigation of statistical matters. Here is his estimate for the next 100 years.

YEAR.	TOTAL POPULATION.	AFRICAN DESCENT
1890	67,240,000	8,000,000
1900	89,738,000	10,144,000
1910	119,650,000	12,862,000
1920	159,890,000	16,309,000
1930	213,320,000	20,681,000
1940	284,697,000	26,223,000
1950	379,960,000	33,252,000
1960	507,090,000	42,163,000
1970	676,760,000	53,463,000
1980	903,200,000	67,790,000
1990	1,206,400,000	85,957,000

These figures are absolutely astounding, and yet we cannot believe they are very far out of the way. If these figures are at all reliable, many of the present readers of the R. N.-Y. will live to see the day when we can boast of a population of 200,000,000 souls. How will this vast population be distributed? Will the descendants of those who have left the hill farms of New England and New York State be forced back to the old home of their ancestors? Will the vast irrigating resources that are now projected among the Rocky Mountains, turn the Western deserts into food-producing districts? Will the vast forests of Washington and Montana be swept away by the farmer's axe as completely as are those of Michigan? Will the negroes be scattered about the country or shall we have half a dozen "black" States where negroes may show their ability or inability to govern themselves? The thought is a wonderful one. What new laws will be needed to handle this vast population? How will business be conducted? What proportion of our population will be found in towns and cities? What use will the farmers of the future make of the possibilities that the years may bring them? The R. N.-Y. has faith in the future. It believes that farmers and farming will develop so soundly and solidly that the agriculture of 100 years hence will be on a better basis than that found for it to-day.

"The rims of my wagon wheels were soaked in hot linseed oil, until they would take no more, when the wagons were made, 20 years ago. The tires have never become loose. I smile when I meet a farmer who is hammering at his tires to tighten them."—T. B. TERRY, page 639.

BREVITIES.

A "SYMPOSIUM" NUMBER!

MAKE a fire in the stove these cold days.

ARE you going to soak your wheels in oil after this discussion?

"RUNTS RUIN RESULTS"—page 644. Any job half done is a "runt."

THERE will be an immense demand for seed potatoes of popular varieties next spring.

UNDER what conditions does it pay a farmer to put a furnace or heater in his house?

A FULL discussion of the effects of the Dressed Beef business on Eastern farms next week.

THE new white grape Witt, is sweet and meaty though foxy. It is earlier than Concord by a few days.

THE Ulster Prolific is as satisfactory a red grape, all things considered, as any tried at the Rural Grounds.

THE R. N.-Y. invites a discussion of the points made by D. C. L., on page 643 regarding the rot in seed potatoes.

FARMERS seem to like manure on potatoes, but they want it first "strained through another crop" like corn, or applied in the fall and acted upon by frost.

IN case of danger from frost, it will pay you to work half the night cutting fodder corn. Cut and placed on the ground, even for a few hours before the frost, it can be saved.

SEVERAL writers agree with the R. N.-Y. that the potato vines succumbed to the "blight" because they were weakened by the attacks of the Flea-beetle early in the season.

THE writer neglected to fix his well a short time ago when a few hours' work would have made it solid. The recent storm has made a two-days' job of it. "A stitch in time!"

WE urgently advise our friends not to save seed potatoes that from blight, Flea-beetle or any other cause, failed to mature. The R. N.-Y. has a sad and telling story to relate on this subject.

THE new peach Good is again giving a favorable account of itself. It is said to be superior to any white-flesh peach of its season. It is what has long been needed for canning after Crawford's Late.

GATHER the seeds of the Rose of Sharon (Hibiscus Syriacus). The seed sprouts readily, the seedlings are thrifty and will bloom the second year. Seedlings in the size, doubleness and colorings vary indefinitely.

Ladies of the R. N.-Y. Potato Contest, send in your reports before October 15. *The time has been extended in compliance with requests. The prizes, amounting in value to about* $1,000, *will be awarded as soon thereafter as practicable.*

THUS far this season 16,000 barrels of apples have been sent from this country to Europe. This is just half of last year's shipment up to this date. Prices for apples in England are very high, but there is an American demand for about all the home product.

SOME of the fairs near the large cities make a mistake in supplying free admission tickets to all exhibitors. It's easy for a city man to buy a peck of potatoes and enter them, thus insuring a free admission. With such an arrangement in force too many entries are made simply to secure a free ticket.

NEXT week Judge T. C. Jones of Ohio, will begin a series of articles describing the history of beef-growing in the central West, with his views as to the best ways of meeting the changes that have been forced upon the industry by the dressed beef business. Few men are better qualified to discuss this question than Judge Jones.

Indust'l Societies.

THE LONG ISLAND LIVE STOCK ASSOCIATION.

(RURAL SPECIAL REPORT.)

THE second semi-annual exhibition of the Long Island Stock Association was held on the association's grounds near Huntington, L. I., from September 10 to 14. It rained every day during the week and the attendance was extremely small. The exhibition, however, was a good one and had the weather been favorable, it would have been a great success. The fruit and vegetable display was exceptionally fine. It filled several tents, and a portion of the main building.

Although the latter is fully 200 feet in length, yet it was completely filled with flowers, fancy-work and other articles of interest to the ladies. One side of it was devoted to bread and cake and other products of culinary art. On this side Mr. Burgess showed a hive of bees at work and a quantity of White Clover honey. In the fancy-goods department a bed-quilt made at sea by Captain Hallock attracted much attention and received honorable mention. Surely when a sea captain exhibits a hand-made bed-quilt and the ladies stock and poultry, the millennium must be close at hand.

Owing to the storm many of the implements were not unpacked, and the display in consequence seemed very meager. Mr. C. B. Vail of Huntington, made a fine display of carriages, including his famous buckboards and farm wagons. The show of stock and poultry—what there was of it—was good. It is said that the result of the fair will be a heavy debt for the association. It is to be hoped that the managers will not be discouraged, as the association had all the elements required to make a successful exhibition and another year will doubtless retrieve all the losses. J. H. G.

CROPS: AN OHIO FAIR.

(RURAL SPECIAL REPORT.)

Thrifty farmers in western New York; crops there and in western Pennsylvania and northern Ohio; the Huron County Fair; fine displays of cattle, swine, sheep and horses; dairy exhibit small, but good; fine potatoes and other vegetables; the inevitable "hoss trot;" general satisfaction.

IN passing along the shore of Chautauqua Lake even at a rapid rate, one can discover the thrift and enterprise of the average farmer in the tidy appearance and the fine surroundings of his home. The crops yet remaining in the fields—corn and potatoes—are looking reasonably well, better than could have been expected considering the late frost and excessive rainfall of early summer, and the comparatively dry weather since August 1. Meadows and aftermath are looking well; buckwheat has an average growth and is well filled. Fruit is exceedingly scarce: there isn't one-tenth enough for home consumption.

As we leave the lake region and come on to the slope towards Lake Erie, the grape-growing industry is the great object of remunerative interest. Immense vineyards stretch as far as the eye can reach, well laden with fruit of superior merit as regards size and quality. I heard an old grape-grower remark that he had never seen the sugar in the grape so abundant as this year, and that the growers hoped to receive better prices than they did last year for better grapes. It is expected that the shipments will exceed those of last season. The Worden is considered the best early grape; while Moore's and Talman come next; but for a general-purpose grape nothing exceeds the Concord. Apples are scarce; while pears are quite plentiful at from $1 to $1.50 per bushel.

Along through Western Pennsylvania and Northern Ohio rain is needed, though crops are not particularly suffering. Many are putting in their wheat or preparing for it. Most of the plowing is leaving the land very lumpy on account of it being so dry. About the usual area will be sown to wheat.

Huron County was well represented at its agricultural fair, which was held at Norwalk. The grounds are commodious and pleasantly situated in a beautiful grove. The display in all its various departments was good. In Short-horns and Herefords little improvement could be made. Of Jerseys and Guernseys there was only a small display, but those present were of good quality. Among swine, Berkshires and Chester-Whites were the favorites, and the exhibits were of superior quality. The sheep exceeded anything I have witnessed this year, cassimere Merinos and Shropshire Downs being the favorites. The poultry department was of excellent quality but not a large display. Of agricultural machinery, the display was varied and fine. As we entered the Dairy Hall we were forcibly struck with the meager display both of butter and cheese, but what was on exhibition was of unquestionable quality. The vegetables on display were exceedingly fine, especially the potatoes. Some specimens of the Pride of the Valley were commented on as superior to any variety raised in that section and certainly their appearance denoted productiveness and excellent quality. In the fine arts and domestic manufacture everything was in good taste and showed conclusively that the fair daughters of Huron County rank high among America's fair women as to skill and taste.

There were many fine horses upon the grounds, though the average farmer is behind the age in the farm team. The only excuse offered by him is that all good horses are picked up for the Eastern markets. The afternoons of the third and fourth days were mostly devoted to horse trotting and balloon ascensions. A number of fine horses were on the track, but no one showed a better gait than a 2.37½, a brown stallion "Happy King" winning the stallion race at that. The results of the fair were satisfactory to the managers and to the people. The representative of the RURAL NEW-YORKER on the ground was doing his utmost to convince the people that it is the reading, thinking man that makes the successful experimental farmer, and that success comes to the man who does his work in the most thorough manner and feeds his land most liberally that it may produce large returns.

Woman's Work.

CONDUCTED BY EMILY LOUISE TAPLIN.

CHAT BY THE WAY.

QUITE a pretty idea in decoration is to hang a gay Chinese or Japanese paper lantern from the center chandelier. It is far prettier than any of the absurd air-castles or fancy baskets one often sees suspended there, and it has the merit of utility too. When only a dim light is needed, instead of turning down the gas or lamps, the candle may be lighted in this lantern—it gives a pretty, mellow light, and is economical too.

* * *

THE newest fairy lamps are of China, three-sided; these sides show respectively the head of a cat, a dog and an owl. The eyes are of glass, and the light shines through them with a very realistic effect.

* * *

THE Art Interchange describes some very pretty lampshades. Upon a frame of wire a piece of muslin is sewed, fitting very closely. Upon this cover, rows of silk ruching are tacked; they are pinked at the edges, and put very closely together, entirely covering the muslin foundation. A box-plaited ruffle of gold lace is put around the top, standing upwards, and a band of ribbon tied in a bow at the side draws it securely together. Another shade made on this same model has the muslin foundation covered with two silk flounces in different shades of the same color, the lower one being the darker. A full ruche of silk or lace is put around the top. A parasol lamp shade described is of thin yellow silk, crimped in close folds, and smocked with orange silk. The smocking is done loosely, so that the frame is elastic; it is finished by a fall of black lace and three little black birds on one side.

* * *

CHARMING screen photograph frames are made of heavy cardboard covered with flowered French chintz. They may be made with either three or four leaves, the larger ones having spaces for two rows of pictures. The smaller ones are charmingly dainty when covered with flowered art silk. Some very dainty photograph frames are covered with white kid, having a painted design.

* * *

MANY of the new basques and jackets, too, have sleeves of a different material, usually made in a wrinkly leg-of-mutton shape. Braided cloth jackets have these sleeves in velvet of the same color. This is a very convenient fashion in making over-dresses where there is some scarcity of stuff. Suppose one has an old cloth dress in solid color, and a few yards of plaid or figured goods, or silk in harmonizing tint. We would make a plain round skirt—it might be shirred, or left in loose plaits. It should have a plain round waist with surplus folds of the contrasting stuff, and leg-of-mutton sleeves of the trimming. It would be finished by a belt and Empire sash of the contrasting stuff, the sash ends hanging at the side, being gathered at the end, and finished by a tassel or crocheted ball. The collar, if any, should be very narrow, and finished with a turn-over Empire frill. With a little oval toque, made of the goods, and trimmed to match, this would be a very pretty fall dress.

* * *

"FALL DRESS." Why do we say fall, instead of autumn? It is the fall of the leaf—yet this is a somewhat indescriptive term. We are so apt to take liberties with our language, in this free land, that some care is necessary, or we shall become a nation of slip-shod talkers. Apropos of seasons, how absurd it is to say one is "summering" here or "wintering" there—we may yet live to hear that our friends are springing in town and falling in the mountains—but we hope not.

THINGS THAT COST NOTHING.

OLIVE E. DANA.

MY title is a misnomer. I believe there are very few things which are of use and value that literally cost nothing. "From nothing, nothing comes," runs the old proberb, and the very appropriation of any gift or blessing implies energy, receptivity, or feeling.

There are things which literally cost nothing in dollars or cents, and the money-value of any article is its common appraisal. So I have adopted the old phrase because I do believe that many of the things that give savor and flavor to life and its duties are unpriced and too often unprized.

We slight our common mercies and deem that only rich or sweet or beautiful which is almost if not quite out of reach.

We complain of the narrowness of our lives, and their barren surroundings when, very likely, we ourselves set those limits far within their possible range of privilege and pleasure, and perhaps not only refuse to make our bit of arable land yield any other, sweeter growths, but even shut our eyes to the beauty that already is in daily sight.

But I am wandering from my subject. I meant to speak only of the capabilities that are in all our lives, I trust capabilities of enlargement and elevation of joy-getting and joy-giving. I wanted to speak of the riches of the things that "cost nothing,"—nothing save tact and patience and a willing hand, and a seeing eye, and a loving and trustful spirit. And if this last named possession seems to you who read this, as it does to me, the most desirable of earthly possessions, let me enlist your sympathy with mine still further by asserting that a right use of the things that cost nothing is one of the best possible helps (on the human side) to its attainment. I am digressing again, am I not?

Let me hasten, then, to specify. I might remind you, as I am tempted to do, that the best preservatives of health, the best aids to its recovery if lost, are the cheapest and simplest things, the elementals. I wonder how many times a week a really wise physician, either unconsciously or on purpose, reminds his patients of the wonderful healing potencies of sun and air, of pure water, of plain, wholesome abundant food, of exercise and cheerfulness? These are Nature's simples. The most and best of the things that cost nothing come from the same store-rooms.

But there are other things of which no physician is likely to remind us, yet which contribute very largely to that health of mind to which the best physical conditions are tributary—without which the latter, if they can exist at all, seem of comparatively little value. These are the little habitudes of household and personal adornment, to begin with: the neatly spread table; the tastefully tidy room; the vase of flowers for tea-time; the freshened toilet after dinner;
